Language is the subjective activity of a cognizing individual, and it exists only in speech, in the communication within a speech community that shares history and culture. Mind (*dukh* – intellect and spirit/soul) in Potebnja should be understood "in the sense of conscious mental activity," "higher order cognizing activity"(1862: 37); "language is the passage from unconsciousness to consciousness" (1862: 37). Every speech act is simultaneously an act of understanding, of objectivization, of consciousness, of interpretation of thought, of cognition (1862, 1874, 1888). He stated that many forms of thought exist and develop without language. However, there are mental activities that require language. Potebnja argued that "language is necessary for mental activity so that the mental activity can become conscious" (1862: 37). Man develops the capacities for symbolic thinking and for language concomitantly. These capacities also enable man to choose to substitute natural language for symbolic forms of thinking (e.g., in mathematics, music, the visual arts). Potebnja's works were a wide-ranging critical review of thoughts about language – by grammarians, linguists, and philosophers – from the pre-Platonic and Aristotelian traditions in both Western and Eastern Europe to the 19th century. He was well attuned to thoughts from other fields of knowledge. He regarded mathematics as fundamental for linguistics as it is for other sciences, with two underlying concepts of magnitude and form. He used a number of mathematical concepts: groups/sets, invariance (variant, invariant), zero marking, commutation, and transformation, among others. Potebnja argued that in the history of the development of knowledge, "our times are an example of the interaction of sciences and of choice of the middle way pathways: linguistics and physiology, linguistics and psychology, linguistics and history, psychology and physiology. *Il faut cultiver notre*

Alexander Potebnja (or Oleksander O. Potebnia) was a Ukrainian philosopher of language and mind, a linguist, a historian of ideas, an editor, and a publisher. Potebnja abandoned his law degree to read history and philology at the Kharkiv University, where he would later become a charismatic professor. There have been many references to his achievements and originality, as well as varying ideologically tainted references often repeated in Eastern/Western accounts in the 19th and 20th centuries. He was regarded as the most important linguist in the Old Russian Empire among the three main ones (the other two being F. F. Fortunatov and I. O. Baudouin de Courtenay). Potebnja was the inspiration for the Kharkiv School of linguistics and poetics. The Institute of Linguistics of the Ukrainian Academy of Sciences is named after him. From 1878 to 1890, Potebnja was the president of the Kharkiv Historical-Philological Society (founded in 1876 and, under Soviet rule, forced to close in 1919). He was a member of the Russian Imperial Academy of Sciences and the Czech Scientific Society. His wife, Maria Potebnja, ensured that his original manuscripts were published.

Potebnja's works were a study of the evolution of human knowledge and consciousness encoded in language. Indeed, his *oeuvre* was likened to that of Darwin. His philosophy encompassed a theory of the mind, of consciousness, of knowledge, of perception, of speech acts, of symbolic thinking, of aesthetics. Literature was included in his theory of language as part of the whole of language and its functions. He was critical of positivism. He seems to have sought to resolve the Cartesian problem of consciousness and the physical world.

Language is the subjective activity of a cognizing individual, and it exists only in speech, in the communication within a speech community that shares history and culture. Mind (*dukh* – intellect and spirit/soul) in Potebnja should be understood "in the sense of conscious mental activity," "higher order cognizing activity"(1862: 37); "language is the passage from unconsciousness to consciousness" (1862: 37). Every speech act is simultaneously an act of understanding, of objectivization, of consciousness, of interpretation of thought, of cognition (1862, 1874, 1888). He stated that many forms of thought exist and develop without language. However, there are mental activities that require language. Potebnja argued that "language is necessary for mental activity so that the mental activity can become conscious" (1862: 37). Man develops the capacities for symbolic thinking and for language concomitantly. These capacities also enable man to choose to substitute natural language for symbolic forms of thinking (e.g., in mathematics, music, the visual arts). Potebnja's works were a wide-ranging critical review of thoughts about language – by grammarians, linguists, and philosophers – from the pre-Platonic and Aristotelian traditions in both Western and Eastern Europe to the 19th century. He was well attuned to thoughts from other fields of knowledge. He regarded mathematics as fundamental for linguistics as it is for other sciences, with two underlying concepts of magnitude and form. He used a number of mathematical concepts: groups/sets, invariance (variant, invariant), zero marking, commutation, and transformation, among others. Potebnja argued that in the history of the development of knowledge, "our times are an example of the interaction of sciences and of choice of the middle way pathways: linguistics and physiology, linguistics and psychology, linguistics and history, psychology and physiology. *Il faut cultiver notre*

jardin [quote is from Voltaire's *Candide*]. In this way we will cross-fertilize adjacent fields" (1905/1970:114).

A sophisticated theory of signs and semiotics was contained in his theories. For example, he argued that every word "consists of three elements: (i) the unity of the articulate sounds, i.e. the **external sign** of meaning; (ii) **representation**, i.e. the **internal sign** of meaning and (iii) **the meaning** itself" (Potebnja's emphasis). In his works, the term 'word' was often interchangeable with 'language' as faculty, competence. Equally, the term 'etymology' stood for what would be termed 'semantics' when the latter was coined in the last decade of the 19th century.

Potebnja argued for a separation, in an innovative way, of the inherited amalgamation of logic and language, postulating the psychological sentence in opposition to the proposition of logic (1874). His works contained both an account of the parts of speech and a history of the evolution of the Indo-European sentence – a comprehensive '*Thesaurus syntacticus*' (1874, 1888, 1941, 1958).

Children's language acquisition was an essential axiom in his theory. As a linguist has no access to how language is formed, nor is it possible to remember how one acquired language as a child, Potebnja postulated instead the observation of child language acquisition. For him the development of language in the child was a process accompanied by conscious thinking that at the same time was symbolic and was cognitive development.

His writings were characterized by a lack of jargon and by his use of memorable metaphors (e.g., triangle, shroud, spider web and weaving, chessboard). His works on linguistics were centered on Ukrainian at the time of secret Imperial Russian edicts against Ukrainian. It is worth noting that the word 'Great Russian' was used for 19th-century Russian; therefore, in Potebnja, 'Russian' should be read as 'East Slavic.'

His seminal *Thought and language* (1862) offered a critique of the earlier language theories, and he elected Humboldt as a point of departure for the development of his own philosophy and theory of language. However, he did not limit himself to Humboldt, using in addition much of the received and contemporary scholarship. He was credited with introducing Humboldt to the Old Russian Empire.

Potebnja's influence was significant among students, followers, critics, and borrowers in both the former Soviet Union and the West in such fields as linguistics, philosophy, literature, aesthetics, semiotics, psychology, music, and ethnoscience. Much of his work foreshadowed, for example, that of Sapir-Whorf, Croce, and Vossler. Vygotsky borrowed liberally from Potebnja (especially in *Mysl' i Rech, Theory of psychology of art)*, Kristeva spoke about Potebnja's role in discourse analysis and pragmatics, and Jakobson was allegedly his advocate and even gave a lecture about Potebnja at Harvard.

The founder of modern scientific etymology, August Friedrich Pott, was born the son of a pastor on November 14, 1802, in Nettelrede near Bad Münder. Having studied philology and philosophy at the University of Göttingen, he obtained his doctorate there in 1827 with a thesis (still deeply rooted in old-fashioned philosophical grammar) about the relations expressed by prepositions. After that he took up Indo-European studies with Franz Bopp in Berlin and became a lecturer there in 1830. He was appointed extraordinary professor of general linguistics in Halle in 1833 and promoted to full professor in 1838. He was loyal to the University of Halle until his death on July 5, 1887.

Pott, August Friedrich (1802–1887)

R Schmitt, Laboe, Germany

© 2006 Elsevier Ltd. All rights reserved.

The founder of modern scientific etymology, August Friedrich Pott, was born the son of a pastor on November 14, 1802, in Nettelrede near Bad Münder. Having studied philology and philosophy at the University of Göttingen, he obtained his doctorate there in 1827 with a thesis (still deeply rooted in old-fashioned philosophical grammar) about the relations expressed by prepositions. After that he took up Indo-European studies with Franz Bopp in Berlin and became a lecturer there in 1830. He was appointed extraordinary professor of general linguistics in Halle in 1833 and promoted to full professor in 1838. He was loyal to the University of Halle until his death on July 5, 1887.

His first major work, the two volumes of *Etymologische Forschungen auf dem Gebiete der Indo-Germanischen Sprachen* (1833–1836) is concerned with comparing the lexical stock of the Indo-European languages and, at the same time, observing the regular phonological correspondences among them. By this two-track approach he put etymology on a firm methodological basis and also founded the comparative historical phonology of the Indo-European languages. But while Pott was still alive, the subsequent development of Indo-European studies went far beyond the foundations laid by him specifically with regard to phonology, owing mainly to the progress made possible by the principles of the Neogrammarians postulating that sound laws operate without exceptions.

Quite early, and presumably under the influence of Wilhelm von Humboldt in this approach, Pott tried to familiarize himself with all the worldwide languages and language families for which he could obtain printed materials. Thus he abandoned the restriction on Indo-European languages and, being far ahead of his time, turned to truly universal linguistic studies. These studies enabled him to arrive at an overall (mainly bibliographical) survey of general linguistics that was published in the serial 'Einleitung in die allgemeine Sprachwissenschaft' (1884–1890) and in the summarily *Zur Litteratur der Sprachenkunde Europas* (1887), both of which were reprinted together in Pott (1974).

Moreover, Pott did pioneering work on the gypsies and their Romany (Romani) language, and by his *Die Zigeuner in Europa und Asien* (2 vols.) (1844–1845), he created a firm scholarly basis for such studies. He had also developed a penchant for studying modern languages such as Kurdish, Latvian, and even the Bantu languages, whose relationship he reliably documented. Pott followed Humboldt's approach toward linguistic research without linguistic boundaries by dealing with particular grammatical categories, with phenomena such as reduplication and gemination, with proper names in general, or with numerals – and especially the quinary and vigesimal systems of counting (1868). Furthermore, he published a new annotated edition of Humboldt's *Ueber die Verschiedenheit des menschlichen Sprachbaues*, with an introduction providing a comprehensive appreciation of Humboldt as a general linguist (1876).

Pound, Louise (1872–1958)

C Eble, University of North Carolina, Chapel Hill, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

Louise Pound (1872–1958) was largely responsible for making American speech and folklore respectable areas of scholarly research and writing. Born on the American frontier in Lincoln just 5 years after Nebraska achieved statehood, Pound's long and productive life was characterized by a pioneering spirit. Along with her older brother Roscoe (later Dean of Harvard Law School) and younger sister Olivia, Pound was educated at home by her mother until she could enter the University of Nebraska's 2-year preparatory school. At the coeducational state university in her hometown where Pound received a Bachelor's degree (1892) and a Master's degree (1895) and later taught for 50 years, she excelled in everything. Throughout her life, she was known in Lincoln for her energy, wit, and competitive spirit. She was in great demand as a public speaker, lecturing on British and American language, folklore, and literature to civic organizations, teachers' associations, and groups such as the American Association of University Women, on whose national board she served for years. A life-long athlete, Pound excelled in figure skating, cycling, tennis, and golf and was the first woman elected to the Nebraska Sports Hall of Fame.

Pound began advanced study of the early periods of English language and literature in the summers at the University of Chicago but soon decided that earning a doctorate in philology from a German university would be more exciting and quicker. Pound received her Ph.D. in 1900 from the University of Heidelberg after only two semesters, studying under the direction of Johannes Hoops and writing a dissertation on the comparison of adjectives in late Middle English. With a strong foundation in its linguistic and literary antecedents in Great Britain, Pound began to observe and publish on American English.

In the 1920s, when she was in her fifties, she was probably the most prominent woman academic in America. In 1921, her *Poetic origins and the ballad* disproved the commonly held belief that ballads arose communally. She served as vice president of the Modern Language Association in 1925 and president of the American Folklore Society in 1925–1927, and in 1924 supported the founding of the Linguistic Society of America. With the influential backing of H. L. Mencken, whom she had helped with revisions to his best-selling *American language*, and editorial assistance from her former student Arthur G. Kennedy, Pound founded the journal *American Speech* in 1925 and was its editor for the first 5 years. (*American Speech* is now the official journal of the American Dialect Society, published quarterly by Duke University Press.) In 1928, Pound represented the United States as one of nine delegates to a conference in London to consider establishing an International Council for English. In the 1920s, Pound began a long term on the advisory board of *American Literature*, published numerous articles, master-minded textbook projects, and taught summer school at the University of California at Berkeley, Yale University, and the University of Chicago.

In 1955, at eighty-three, Louise Pound was elected the first woman president of the Modern Language Association.

Poutsma, Hendrik (1856–1937)

R Supheert, Utrecht University, Utrecht, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Hendrik Poutsma, one of the leading Dutch Anglicists of the early 20th century, was born in Gorredijk, the Netherlands, on December 7, 1856, the son of a headmaster of a municipal primary school. He began his career as a primary school teacher but qualified for a secondary school teaching certificate in English after a stay in England. This marked the beginning of a lifelong career as English master at a number of Dutch secondary schools. Poutsma's education and career mirror those of many early Anglicists in the Netherlands, which knew no tradition of English studies at the university level until 1886, when the first chair of English was established at the University of Groningen.

Poutsma's *magnum opus* is a multivolume, 3200-page grammar of English, published over a period of 22 years, intended for continental, and notably Dutch, students of English: the *Grammar of late modern English*. It offers a highly detailed and systematic description of English grammar. In his preface to the first edition, Poutsma professes to focus on the language of the last 200 years, but in fact he bases his description on a huge corpus of examples, also included in the book, ranging from Chaucer to contemporary newspapers, with 19th-century poets and novelists taking pride of place. Because of its sheer size, the *Grammar* is a reference work rather than a textbook. A more practical enterprise is *Do you speak English?*, which saw six editions between 1893 and 1930, and offers English vocabulary with Dutch translations. It provided some of the material for Ten Bruggencate's authoritative Dutch–English dictionary.

Although Poutsma did not train or teach at university and emphatically based his analysis on specimens of actual written language, his grammar is theoretical and complex. His framework of references shows that he placed his work within the context of theoreticians such as O. Jespersen and H. Sweet. E. Kruisinga, fellow Dutch Anglicist and Poutsma's junior by 19 years, is warmly acknowledged in the preface to part I of the second edition of the *Grammar* (1928). The *Grammar* was criticized for paying little attention to phonetics and word formation, and for overstepping the boundary between synchronic and diachronic syntax, but was nevertheless used at universities in Europe and America. Dutch appreciation for Poutsma's massive contribution to English language studies in 1932 was expressed with a honorary doctorate from the University of Amsterdam.

Power and Pragmatics

J Wilson, University of Ulster at Jordanstown, Newtownabbey, Northern Ireland

Introduction

Pragmatics is concerned with meaning in the context of language use. Basically, when we communicate through language we often mean more than we say; there is often a gap between speaker meaning and sentence meaning. For example, why is it that we interpret *Can you pass the salt?* as a request and not simply a question? Why do we tend to interpret *John has three children* as meaning **no more** than three children? Why, when we say *some of the boys came to the party*, do we know that **not all** of the boys came to the party? And why do we find that certain utterances are paired, such as greeting/greeting, question/answer, or request/response? Pragmatic theories attempt to explain this knowledge by seeing communication as a process of rational and reasoned interpretation, which draws not only on linguistic structure but also shared and world knowledge, cultural norms, and individual components of specific interactional contexts (see Levinson, 1983, 2000; Sperber and Wilson, 1995; Yule, 1998; Mey, 2001;

Power and Pragmatics

J Wilson, University of Ulster at Jordanstown, Newtownabbey, Northern Ireland

Introduction

Pragmatics is concerned with meaning in the context of language use. Basically, when we communicate through language we often mean more than we say; there is often a gap between speaker meaning and sentence meaning. For example, why is it that we interpret *Can you pass the salt?* as a request and not simply a question? Why do we tend to interpret *John has three children* as meaning **no more** than three children? Why, when we say *some of the boys came to the party*, do we know that **not all** of the boys came to the party? And why do we find that certain utterances are paired, such as greeting/greeting, question/answer, or request/response? Pragmatic theories attempt to explain this knowledge by seeing communication as a process of rational and reasoned interpretation, which draws not only on linguistic structure but also shared and world knowledge, cultural norms, and individual components of specific interactional contexts (see Levinson, 1983, 2000; Sperber and Wilson, 1995; Yule, 1998; Mey, 2001;

Blakemore, 1992). The question we want to consider here is how this view of human communication is related to the operation of power in society.

Pragmatics, Power, and Language

Pragmatics is recognized as a branch of language study and in recent times the operationalization of power within, or through, the use of language in society has become a central concern of discourse analysis, sociolinguistics, and pragmatics. Textbooks are now giving specific emphasis to the area (see Mesthrie *et al.*, 2000) and there are emergent branches of study, such as critical linguistics, critical discourse analysis, or critical sociolinguistics (see Fairclough, 2001; Wodak, 1996; Talbot *et al.*, 2003), where it is the analysis of power within linguistic practices that is the core focus. The term 'critical' links these approaches closely with social theory and their central aim is to demystify the way in which language operates in society. The term 'power' is not always easily defined, however (see Thornborrow, 2001). Power can be ideological, economic, or cultural, for example, and within these confines, power can operate at a range of different levels: the social, individual, military, state-based, legal, and so on. Though all this is true, there is a general understanding that the operation of power is the ability to get an individual to behave or not to behave in a particular manner. Although this process may be realized in different ways and in different social environments, the pragmatic resources utilized may be of the same type. The problem is, of course, that not everyone has the same access to such resources, and, even when they do, not everyone has the same ability to use those resources in the same way. Hence, some individuals or groups may access or use pragmatic resources to maintain a position of power over others (Harris, 1984; Lakoff, 2000; Hutchby and Wooffitt, 1998).

Consider, for example, the act of ordering someone to do X. Parents may order a child to be quiet, an army officer may order soldiers to *march*, or a police officer may order a motorist to *stop*. Orders or commands such as *Stop!, Be quiet,* or *Quick march*, are imperative forms that function to signal a specific action or, as it is known, a 'speech act' (Austin, 1962; Searle, 1969) (*see* **Speech Acts**). Speech acts frequently have linguistic markers that indicate which act is being performed, such as *I apologize*, or *I order you to X*, but frequently the act is underlying or indirect, as in *(I order you) March!* But equally important in producing speech acts is the recognition that certain conditions hold, such as X has the authority, right, or power to order Y. In the examples above, this power condition is institutionalized within the system of parental control, within the legal system for traffic law, and within the formal authority of army hierarchy. Thus, although we can all produce orders, we do not all have access to formal roles that ensure the order is carried out. Hence, in contexts such as schools, medical encounters, or certain forms of business organizations, the power to utilize selected pragmatic resources is differentially distributed (Drew and Heritage, 1992; Bourdieu, 1991; Lippi-Green, 1997) (*see* **Institutional Talk**).

This type of control may be seen in the organization of talk in interaction. Here, there are issues of not only who can say what, but who can speak when and about what topic. Studies of the distribution and organization of taking turns at talk clearly show that in schools it is the teacher who organizes and distributes the turns at talk (Coulthard, 1977). Similarly, in the doctor's surgery, it is the doctor who is in control; it is his job to ask the questions and the patient's job is simply to respond (Wodak, 1996). In these contexts, there is an interactional asymmetry in relation to responsibility for talk organization. Indeed, in the case of either the school or the surgery, for the student or the patient to begin to ask questions or to take the lead in talking would be seen as a challenge to the power and control of the doctor or teacher.

But it need not be a specifically formal situation where such forms of control operate. Studies of gender differences have continually indicated that in mixed-gender interactions, men attempt to dominate the control of turns, access to the floor, and topic content and distribution (Talbot, 1998; Tannen, 1994). As Shaw (2000) has shown, things become even more complicated when gender and formal context are mixed. In a study of what may be termed 'illegal' interruptions in British House of Commons Proceedings, Shaw noted how male MPs made such interruptions more frequently than female MPs. Furthermore, when women MPs did carry out such actions, they were more frequently censured for this by the Speaker of the House.

Instrumental and Influential Power

The pragmatic control of turns or of specific speech actions could be seen as the use of instrumental power. Instrumental power is often formally embedded as a system of control either explicitly formulated as within the law or more subtly ingrained within what Foucault called "regimes of truth" (Foucault, 1980), that is, the control over access to certain forms of knowledge. But there is also what is seen as influential power in the operation of pragmatics,

and here this may be seen in almost all walks of life, although influential power is more often highlighted in the workings of the media, particularly in advertising, and in politics (Talbot *et al.*, 2003; Bell, 1991).

Consider a burger chain advertising statement: *where good people go for good food*. How are we meant to understand this? There is a clever juxtaposition between *good* as a moral/reflective issue and *good* as a comparative adjective of assessment. In the advertising strap line, there is an effort to get us to process the phrase *good people* and *good food* together. But why? According to Grice (Grice, 1975; see also Sperber and Wilson, 1995) what happens is that the juxtaposition of *good people* and *good food* creates an incongruity in terms of the relevance of the claim. It is incongruent, argues Grice, because communication is based an assumption of cooperation, where we try to speak the truth in a clear and concise manner as simply as is necessary to convey a message relevant to the talk. This gives one answer to our question above as to why we assume that John has no more than three children when someone says *John has three children*. If John had more or less than three children, then according to the pragmatic principles espoused by Grice, the speaker would have said so (see **Grice, Herbert Paul (1913–1988)**).

Grice does not say that his principles are rules that must always be in operation, or which must be obeyed, merely that they provide a heuristics for interpretation. Interestingly, he also suggested that when a speaker says more or less than required, is obscure, or seemingly irrelevant, this may be an indicator that they intend their hearer to look beyond the meanings of the words themselves in order to retrieve the message. In this case, the speaker may be generating a specific kind of inference referred to as a 'conversational implicature' (see Levinson, 1983). For example, if I say *John was in the room* in response to your question *Where have all the apples gone*?, this does not seem to be an answer at all. However, if you assume I am being relevant and saying as much as possible, then you will try to see my response as an answer. Perhaps in this case we both have shared knowledge that John likes to eat apples; if that was the case, you could then infer both that although I do not know who took the apples (if I did I would have said so) I believe/infer that John has taken the apples. The reason I believe this is because, as we jointly know, John really likes his apples, he was in the room, and now the apples are missing. Formally, there would be more to explain here, but the general point is that from a particular utterance we can gain more information than is readily available from sentence interpretation alone (*see* **Implicature**).

What then has the process of eating *good food* to do with the moral or other inclinations involved in being *good people*? One answer is that eating food involves choice. We often hear it said after an enjoyable meal at a restaurant that either the food or the restaurant itself, or both, was a *good choice*. Hence, eating out also involves some discernment on behalf of the customers. And those who are *good* at this get *good food*. Hence, in this case, not only can you enjoy the *good food* but you can give yourself a pat on the back as one of the *good people* capable of making a good choice.

> Good people (those who know or care) go for good food to X.

There is also a more general interpretation here, simply that this restaurant is where *good* people go for their food. Since most of us wish to think of ourselves as *good*, then this restaurant is the place to be. Both assumptions would be worked out using a similar approach. In both cases, the message is clear: if you consider yourself *good* in either (or even more) of the interpretations provided, then you should be in restaurant X.

This kind of influential power attempts to control our actions by pushing our choices in a particular direction. Since *good* may be taken in a number of ways, it expands the range of audiences that it might influence. Thus, any ambiguity is utilized for a positive purpose, as is the case with the politician before an election who says *We have no intention and see no reason at this time to raise taxes*. In this case there are two elements worthy of attention. The first is the negation of the term *intention*. If intention means one is going to do X (raise taxes), then this is denied. However, in the second part of the sentence the adverbial *at this time* marks any intention as time- and context-based. Consequently, if at a later time one does raise taxes (after being elected for example), one could not be accused of having previously misled the public.

Such time-controlled modifications are frequent in the political domain. The British Prime Minister stated, in relation to Britain's involvement in the Iraq conflict in 2004, that "At the present time, we believe, we have sufficient troops" (in Iraq). We see the use of the adverbial again, but also in this case the use of an epistemic marker of knowledge, i.e., *believe* as opposed to *know* (see Chafe and Nichols, 1986). *Believe* is weaker than *know* and may be used to 'hedge' any claims. Should future events prove against one's statement, one can always say that is what I believed at the time.

Pragmatics, as may be seen, is central to the operation of power in society. In formalized contexts, it explains acts in terms of their conditions of operation; similarly, it explains in such contexts, and others, who is expected talk when and about what. It also allows us to see how embedded inferential information may be calculated to explain specific messages and similar embedded information may be used to sidetrack us or to protect the speaker. Knowledge of pragmatics is therefore central to understanding power and its role in human communication.

Pragmatic Acts

A Philosophers' Mistake

An often heard critique of the Searlean approach to speech act theory (and, by implication, also of Austin's and Grice's; see Mey, 2001: 93–94) is that it concentrates on 'speech' to the exclusion of other phenomena (e.g., writing) that also fall into the category of 'language.' As a result of this critique, some linguists have suggested that we replace the term 'speech act' by a more 'general' one, such as 'act of language' (compare also the French distinction between *acte langagier* and *acte de parole*; German has *Sprachhandlung* as opposed to *Sprechakt*; Bühler, 1934) (*see* **Speech Acts; Grice, Herbert Paul (1913–1988); Austin, John Langshaw (1911–1960)**).

What is at stake here is more than a terminological quibble. Those who want to consider speech as different, less comprehensive than 'language' overlook the fact that all language originates in speech; writing is a later development, arising from the need to preserve the spoken word for later and remote use. However, there is a wider implication, one that is equally often overlooked by linguists and many philosophers alike. As Searle (1969: 16) remarked,

> When I take a noise or a mark on a piece of paper to be an instance of linguistic communication, as a message, one of the things I must assume is that the noise or mark was produced by a being or beings more or less like myself and produced with certain kinds of *intentions*.

In the standard philosophical approach to language, as we encounter it in works by thinkers such as Frege, Russell, Carnap, Reichenbach, Lewis, and a host of other earlier philosophers, the fundamental unit establishing and legitimating our acts of thinking and speaking is the abstract proposition, as it manifests itself in the well-formed linguistic sentence. In this approach, the user of language is conspicuously absent, and consequently so, too, are his or her intentions. For linguists such as Chomsky and his followers, the persistent problem is how to connect a certain representation of the world with a given, well-formed linguistic expression. However, people do not always necessarily think in propositions representing well-formed abstract formulae; nor do they speak in correct sentences, derived according to the rules of an abstract grammar. Regarding people's world representations, the 'intentionality' that Searle points to comprises more than just cognizing: Affect, will, ethical considerations, and so on have to be taken into consideration when we talk about 'mental states.'

Combining these different facets of human mental activity is often thought of as a process of 'addition': To a given propositional content (e.g., 'to shut the door') I can add a volitional component (as in 'I want you to shut the door'), a component of ordering (as in the imperative 'shut the door!'), a component of questioning (as in 'is the door shut?'), and so on. These additional components are then manifested by their appropriate speech acts: wanting, ordering, questioning, etc. It is this kind of thinking that is at the basis of Gazdar's (1979: 4) often quoted formula: 'Pragmatics is meaning without semantics.'

The main difference between speech act theorists such as Searle (one could also mention others, such as Austin, Ryle, and Grice) and linguists such as Chomsky is that the former include the speaker's mental state in their considerations of 'how to do things with words' (Austin, 1962). However, another problem arises here, having to do with the nature of the speech act as primarily defined (in the Searlean approach) in relation to an 'ideal speaker' (the hearer, if present, is similarly idealized). Thus, Searle's approach not only is basically speaker oriented (the hearer being thought of as a speaker who is temporarily 'out of function' – one who is listening to a speaking person in order to become a speaker him- or herself) but also, both speaker and hearer are located in some abstract, idealized universe, devoid of any relation to their actual status as language users. Even where dialogue or conversation is concerned, the question of what the speakers are saying to each other is discussed from a strictly idealized, speaker-oriented viewpoint; thus, questions as well as answers are uttered by dummies figuring as speaker/hearers (e.g., the ubiquitous 'Peter' and 'Mary'). It is in this sense that we must understand Levinson's (1983: 293) often quoted remark that there is no such thing as abstract 'questionhood' or 'answerhood': all questions and their corresponding answers originate in real-world language users. A question is always a concrete somebody's question, and an answer is always given by somebody with real expectations, needs, and obligations.

However, if this is true for questions and answers, then it must hold for other speech acting as well. There are no orders except those given by a superordinate to a subordinate. The speech act of ordering is widely different, for example, in the military than

in the family; although it is true that everywhere certain people give orders while others have to take them, the difference is in the people and their placement in society. Similarly, there are no promises except those given by a concrete 'promiser' to a concrete 'promisee,' as they are characterized by their actual living conditions, especially when it comes to understanding what a promise is about, being able to accept a promise, and so on. Also, regarding ordinary conversation, the accepted ordering sequence of the individual replies not only represents some external schema (as used in conversation analysis) but also reflects and reproduces the power structure of our society: The powerful grab the floor, whereas the weak withdraw under pressure (*see* **Conversation Analysis**).

A final aspect (partially adumbrated in the preceding) is essential to our understanding of speech acting. A speech act never comes alone but carries always with it a bevy of other acts on which it essentially depends for its success (*see* **Speech Acts and Grammar**). Some of these are strictly speech oriented, whereas others are of a more general nature and include, besides speech, those aspects of communication that often are referred to as 'extralinguistic': gestures, intonation, facial mimics, body posture, head movements, laughter, and so on. It is these inclusive acts that I call 'pragmatic acts (*see* **Pragmatics: Overview**).'

An Illustrative Case: The Irony of Irony

I now illustrate the previous discussion by adducing a classical instance of purported speech acting: the use of irony in speech. Much has been written about irony by linguists, philosophers, sociologists, computer scientists, psychologists, and others. I limit myself here to contrasting two characteristic approaches from different camps: one linguistically and philosophically oriented, and the other more geared toward a computational view (*see* **Irony**).

Sperber and Wilson, two of the best known authors writing on the subject of irony from a philosophical–linguistic standpoint, have expressed their views on the subject in a number of important contributions. Here is a typical quote:

> "Irony plays on the relationship between speaker's thought and the thought of someone other than the speaker" (Sperber and Wilson, 1986: 243).

According to these authors, the speech act of irony is, in the final instance, expressive of a purely mental process, contrasting two thoughts: the speaker's and someone else's.

In contrast to this mentalistic view of irony, others have taken the stance that irony is first of all a situational phenomenon: "Ironic language presupposes an ironic situation, either in the *hic et nunc* or . . . in the human condition at large" (Littman and Mey, 1991: 134). Specifically, a situation is ironic whenever the acting persons' explicit or implicit goals clash with the reality of their acts. For example, consider the firefighter whose smoking in bed causes the fire station to burn down: His implicit goal, to prevent fires, clashes with his explicit acting, causing a fire to break out. This 'clashing' of act and intention is not only typical for irony but also typical for all sorts of humor; cf. especially Freud's definition of humor as "a shock between two heterogeneous or incompatible worlds" (as quoted in Haverkate, 1990: 107; Freud, 1916/1948). Similarly, in Littman and Mey's (1991: 135) terminology, irony is based on a 'twist' that "appears to depend upon some relationship between (1) the actor's goals, (2) the actor's plans, and (3) the actor's state of knowledge about the likelihood of the plan succeeding."

Irony thus presupposes an ironic situation, one in which an actor's plans somehow come to naught through his or her own fault or lack of knowledge, as attested by Robert Burns's "best laid schemes of mice and men" that sooner or later all "gang agley" – most often through the actors' own doings. If we accept this view of irony, then it should be evident that the acting is a central ingredient of any kind of ironic utterance; in fact, ironic utterances are only possible within some kind of action frame, viz., an ironic situation that makes the irony possible. Irony is thus, strictly speaking, not a speech act by its own volition and authority; its quality of 'act' depends on the acting persons and their views and knowledge of the situation in which they act.

It follows that ironic utterances are not, as Sperber and Wilson (1981: 302) maintain, basically to do with speaker attitude but with the world; not principally with speaking but with acting. The distinction between 'using' an utterance and 'mentioning' it (in irony) that these authors advocate (Sperber and Wilson, 1981) thus turns out to be just as vacuous as the time-worn distinction between 'saying' and 'meaning' when applied to irony (cf. Booth, 1974). As to 'mentioning,' this is itself a case of language use and thus not essentially different from other 'use'; as such, it is situation dependent. Speech, by itself, does not act: strictly speaking, there are no speech acts since, ultimately, all speech acting crucially depends on the situation in which the action takes place. Hence, speech acts, in order to be viable, have to be 'situated,' as discussed next.

Acting in a Social Situation

Previously, I stressed the need to think of speakers and hearers as acting in a social context. In traditional linguistics, the user, when and if he or she appears on the scene (as we have seen it happen in Searle's or in Sperber and Wilson's works), is always defined as an individual speaker whose words are spoken in the abstract space of 'exemplary thinking': The utterances that are produced lack any anchoring in the societal reality and invoke a context only as needed to make (minimal) sense. Such a context is never extended beyond the immediate needs of the description; it is not one that is solidly placed in the speakers' and hearers' actual social environment, a *situated* context. Similarly, the voices that we are hearing in the constructed dialogues of linguists' examples belong to lifeless characters (e.g., the famous 'Mary' and 'Peter') and not to real, interacting persons on a common, social scene (Mey, 1994: 155) (*see* **Context, Communicative**).

Typical for the social situation is that it is a common scene – that is, a situation whose participants are on some kind of shared footing. Elsewhere (Mey, 2001: 135), I have advocated the necessity of situating our speech acts in context, especially with regard to analyzing people's conversation. The reason is that no speech act, or any conversational contribution, can be understood properly unless it is situated within the environment in which it was meant to be understood. 'Quoting out of context' is a well-known means of manipulating a conversational partner; the proper use of conversational techniques excludes such manipulation precisely in the name of good conversational behavior.

In particular, the French sociologist Jacques Rancière (1995) applied the notion of 'common scene' to the political domain. Here, politics is defined as the "battle for the common scene of understanding" (Rancière, 1995: 13) – a battle that is not merely about defining a common ground, in the sense of establishing some common definitions or some common conceptual framework, but primarily about what is understood as being common, by ruling out various kinds of 'misunderstanding' (the title of Rancière's work). The point is that such a 'ruling out' should not be conceived of as a one-sided 'ruling' (in the sense of a judge ruling some question out of order) but as an appeal to the commonly accepted rules for making and breaking a social relationship. It is here that the notion of 'social' situation becomes crucial.

Rancière's 'social scene' is more than a simple context, understood as a common platform of conversation; rather, the question that he raises concerns the underlying presuppositions making the scene possible. This possibility involves what the actors can afford, not just what they can think and cognize. Thus, the common scene is 'transcendental' in an even deeper sense than Kant's: Not only the possibility of thinking and cognizing but also the very possibility of acting is questioned. This is why Rancière's notion of common scene is so important for the theory of pragmatic acts (*see* **Kant, Immanuel (1724–1804); Pragmatic Presupposition**).

Understanding a scene depends entirely on the acting. An active understanding implies having an idea of what to do on the scene, not just of what to say or think (these latter, although important, are still subordinated to the acting). Conversely, one's understanding of others depends on understanding their acting and the role they assume on the scene. What may appear as crazy behavior outside of the theater (cf. the expressions, a 'theatrical' laugh, to assume a 'tragic' posture, or even to put on 'an act') is perfectly understandable and rational on the scene, where role and rationality depend on each other. Rational acting is to act in accordance with one's role; any acting outside of that role is irrational (besides being strictly speaking impossible if one wants to keep one's place, both as an actor on the scene and as a member of the theatrical company).

Pragmatics tries to place the common scene within society by making it clear that also on the societal scene at large (and not just in politics) a 'battle' for domination is going on. If we do not understand this battle as a struggle between the forces of society, our understanding of the common scene and its actors will be incomplete. Conversely, our acting is determined by the scene: The scene's 'affordances' (a term from psychology; Gibson, 1979) are the limits of our actions. Common affordances create a common platform for action; a lack of such affordances restricts our possibilities of acting socially. Inasmuch as our acting depends on our understanding of the scene and its affordances, the scene is only 'actable' for all actors if it has been established as common – that is, affordable for everybody and by everybody.

From the previous discussion, it is clear that not only the scene determines our acting but also, conversely, our actions determine and reaffirm the existing scene. We profess adherence to our common platform by acting within its confines, by obeying its limitations, and by realizing our possibilities. Our acting on the scene (this includes our so-called 'speech acts') is thus always a 'situated action' – that is, an action made possible and afforded by and in a particular situation. The next section explores in more detail what this has to say for the question of pragmatic acts.

The Indirect Speech Act Paradox

In the literature, one frequently comes across the following vexing question (e.g., Mey, 2001: 113, 219; Searle, 1975: 82): How to explain that our speech acts more often than not are realized by expressions having very little to do with the literal interpretation of those expressions, but rather much with their conventional interpretation?

The traditional approach to this 'indirect speech act paradox' suggests that we either rely on such expressions being understood as idioms or rely on our using certain rules of inference (Levinson, 1983: 268–272, 2000: 16) (*see* **Inference: Abduction, Induction, Deduction**). A pragmatic solution to the paradox would have to go further and specifically ask what those rules are and how they are administered. Just like other speech acts (or, generally, any way of using words to do things), the so-called indirect speech acts derive their force not from their lexico-semantic buildup but from the situation in which they are appropriately uttered. This 'situational support' rests on the assumption that every situation carries its own organizing principle. That is, the conventions and rules of society determine what is appropriate speaking behavior for a particular situation.

In early speech act theory, this led to the erroneous assumption that the preferred response was the only legal one: the so-called 'canonical' speech act, expressed by an appropriate speech act verb – promises require a verb of 'promising,' orders one of 'ordering,' and so on (Mey, 2001: 184) (*see* **Speech Acts: Definition and Classification**). Although this rigid interpretation of the principle is unacceptable (it would lead, among other things, to the rejection of indirect speech acts as 'improper'), the notion that the situation has a heavy hand in defining and determining what we say is valid. The situation, so to speak, creates the 'affordances' by which we are guided toward a correct interpretation of what we are hearing, and indeed of what we ourselves are saying (in accordance with the observation that we have not properly understood our own utterances until somebody has understood them with us – an insight due to the Danish linguist Jesper Hermann (1992)). Here, we are in touch with the very roots of speech act theory, as it was conceived by Austin (1962: 100, scare quotes as in the original), who carefully (not to say cautiously) referred to the situated utterance as "[words] to some extent 'explained' by the 'context' in which they have been actually spoken." Recall also that it was Austin's original intention to "study the total speech in the *total situation*" (Austin, 1962: 148 (italics added)).

Summing up, speech acts, in order to be effective, have to be situated. That is, they both rely on and actively create the situation in which they are realized. Thus, a situated speech act comes close to what Hymes (1964/1977) called a 'speech event' in ethnographic and anthropological studies (cf. Bauman and Sherzer, 1974): speech as embedded in an institutionalized social activity of a certain kind, such as teaching, visiting a doctor's office, and participating in a tea ceremony. In all such activities, the role of speech is prescribed; only certain utterances can be expected and will be acceptable. On the other hand, by their very acceptance of whatever is said as a situated utterance, the participants establish and reaffirm their social situation. The emphasis is no longer on describing individual speech acts (as it was for Searle and his followers) but on figuring out how a particular act of language came to be used in this particular situation and with what effect. Regarding Hymes's speech event, although the words spoken by the participants require an understanding in terms of the language used, the individual speech acts make sense only when framed in the event.

In this way, the indirect speech act paradox can be dissolved by moving the focus of attention from the words being said to the things being done. In the sense that 'indirectness' is a straight derivative from the situation, and inasmuch as all speech acting depends on the situation (with its dialectic feedback, as we have seen), one may say that in this situational sense, there are only indirect speech acts; alternatively, no speech act, in and of itself, makes any sense. *A fortiori*, there are, strictly speaking, no such 'things' as speech acts *per se*, only acts of speech in a situation. The next section provides more details.

Situated Acting: "The Body Speaks" (John Donne)

The philosophers' mistake, referred to previously, was to believe that we can explain our use of 'words in action' by referring to individual speech acts with well-defined properties, assigned in accordance with certain philosophical and linguistic criteria. We have seen how efforts to break out of this linguistic and philosophical straitjacket (such as by Searle and the post-Searleans or by the followers of Sperber and Wilson) have failed in the end. The reason is that no isolated theory of language or the mind will be able to explain the workings of the human user in a concrete situation that depends neither on the mind nor on language exclusively and that consequently cannot be expressed in terms specifically created for describing the linguistic or mental domains.

In contrast, a pragmatic approach to speech acting will, as its first and most important business, raise the question of the user's possibilities in a situation. To

use a parallel from another mental activity, vision: seeing is not a simple matter of an object reflecting itself in the mind, it is the situation that, along with the active perceptive categories, 'creates' the objects of perception in accordance with the possibilities afforded by the situation (aptly called 'affordances' by Gibson, 1979). Similarly, when we use language for communication, what we expect to hear is what we can, and actually do, understand in the situation. However, this situational 'affordability' comprises more than just the words spoken. As Charles Goodwin (2000: 1492) pointed out, in the "situated interaction" that takes place, for example, among girls playing hopscotch,

> the construction of action through talk ... is accomplished through the temporally unfolding juxtaposition of quite different kinds of semiotic resources ... through this process, the human body is made publicly visible as the site for a range of structurally different kinds of displays implicated in the constitution of the actions of the moment.

Goodwin goes on to illustrate this 'use of the body' as one through which participants in situated action make reflexive references to their speech by positioning themselves in the other participants' line of vision, using gestures not just to illustrate but also to actually execute speech acts (e.g., of asserting, contesting, and supporting). More generally, conversational 'moves' are not only realized through speaking in ordered sequences; the body may 'jump into' the conversational fray and change the course of the interaction, preempt a conversational turn, seize the floor, and the like. An act such as 'seizing the floor' is accomplished nonverbally; turn-taking is not only prefaced by, or even merely accompanied by, a body movement: The body move *is* the taking of the turn, as it is performed by dint of a "hybrid system" (Goodwin, 2000: 1516). This interaction between action and speech cannot be captured by a simplistic notion of 'speech act,' no matter how well defined. A proper label to put on those concerted actions is that of the 'pragmatic act' as the locus where all the different linguistic and semiotic structures converge and are properly ordered in communication.

Conclusion: Pragmemes and Practs

The theory of pragmatic acts does not explain human language use by starting from the words uttered by a single, idealized speaker. Instead, it focuses on the interactional situation in which both speakers and hearers realize their aims. The explanatory movement is from the outside in, rather than from the inside out: Instead of starting with what is said, and looking for what the words could mean, the situation in which the words fit is invoked to explain what can be (and is actually being) said.

The emphasis here is not on rules for use of individual speech acts but on characterizing a typical, pragmatic act as it is realized in a given situation. Adopting familiar linguistic terminology (cf. terms such as phoneme, morpheme, etc.), I call this (proto-)type of act a 'pragmeme.' Individual pragmatic acts realize a particular pragmeme (e.g., 'inciting to declare war'); we may call these 'practs.' However, since no acts ever will be completely identical (every situation in which war is declared is different from every other), every pract is also an 'allopract' – that is, a different realization of a particular pragmeme. The Israeli linguist Dennis Kurzon, who has worked specifically in the area of 'incitement,' supported this view when he said that "any utterance may constitute an act of incitement if the circumstances are appropriate to allow for such an interpretation" (Kurzon, 1998: 587; Mey, 2001: 221).

With regard to pragmatic acts, one is not primarily concerned with matters of grammatical correctness or strict observance of rules. What counts as a pract (i.e., what can be subsumed under a particular pragmeme as an allopract) depends on the understanding that the participants have of the situation and on the outcome of the act in a given context. Schematically, this can be represented as shown in **Figure 1**.

In **Figure 1**, the various abbreviations to the right have to do with textual features, such as INF for 'inferencing,' REF for 'establishing reference,' REL for 'relevance,' VCE for 'voice' (cf. Mey, 2000), SSK for 'shared situation knowledge,' and MPH (for 'metaphor'). The symbol 'M' denotes a 'metapragmatic joker' – that is, any element that directs our attention to something happening on the metapragmatic level. For instance, changing the order of the words in a sentence may tell us something about the relative importance of the transposed elements. Using the standard expression 'alleged' in a report may serve to exonerate the journalist from implicitly proffering an accusation by imputing guilt to an ('alleged') defendant in a criminal case, and so on. However, because it is impossible to catch all of these metapragmatic functions of the 'joker' under one hat, I prefer to wave my hands at terminology by simply labeling this elusive character (with homage to Fritz Lang) M for 'metapragmatic.'

In this way, the right side of the schema symbolizes the elements that are present in the textual chain (the listing is of course not complete). Regarding the column to the left in **Figure 1** it should be read as a feature matrix whose cells can either be filled or empty. If the latter is the case for all of the cells, the matrix renders the value zero (Ø).

Figure 1 Pragmeme, pract, allopract. Adapted from Mey (2001: 222).

In conclusion, let me quote a contemporary Chinese pragmaticist, talking about the 'perlocutionary' effect of speech acts. Yueguo Gu (1993: 428) remarked that "perlocution is not a single act performed by S[peaker]. Nor is its effect being caused by an utterance. It involves a [rhetorical] *transaction* (italics added)." This is, *mutatis mutandis*, what the current entry has been arguing for. Like perlocutions, pragmatic acts involve minimally not only a speaker and a hearer but also, in addition, a number of other factors. When all is said (illocutionarily) and not least (perlocutionarily) done, the 'rhetorical transactions' involved in speech acting rest on the assumption of the force of the utterance. This force is pragmatic, to wit: the force of the pragmeme.

Pragmatic Determinants of What Is Said

E Borg, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

Imagine that Jack, pointing at a book on the table, utters the sentence "That is better than Jill's book." What, we might ask, is said by his utterance? Well, since the sentence contains a context-sensitive expression – the demonstrative 'that' – we know that determining what is said will require an appeal to the context of utterance to provide a referent (*see* **Indexicality: Theory**). Thus, this is one kind of pragmatic determinant of what is said by Jack's utterance. The sentence is also context sensitive in another, slightly less obvious, way: it is in the present tense, so an appeal to the context of utterance will also be needed to fix a time for Jack's claim. Finally, many theorists recently have argued that the sentence is also context sensitive in a third, much less obvious, way: for to grasp what is said by Jack it seems that we also need to know what kind of relationship he envisages between Jill and her book. Does Jack intend to say that the book he is demonstrating is better than the book Jill wrote, better than the book Jill owns, the book Jill is reading, etc? And what does he mean by 'better' here – better written, better researched, better for standing on to reach a high shelf? Surely Jack says more than merely that the book he is demonstrating is better in some respect or other than a book bearing some relationship or other to Jill, but, if so, then any such additional information can only come from consideration of the context of utterance.

Furthermore – and this is where the current case differs from that of demonstratives and tense – it's not obvious that this last type of pragmatic determinant of what is said is traceable to any overt (i.e., syntactically represented) context-sensitive element. Jack's utterance does contain the syntactically marked possessive, but *'s* certainly doesn't appear on the list of usual suspects for context-sensitive expressions. And in many cases even this degree of syntactic representation is missing. Consider an utterance of "It's raining," where what is said is that it is raining at some location, l, or "You won't die," saying that you won't die from that cut, or "Nietzsche is nicer," meaning that Nietzsche is nicer than Heidegger. Or again, consider the speaker who produces a nonsentential utterance, e.g., pointing at a child and saying "George's brother," thereby conveying that he is George's brother. In all these cases we have additional information contributed by the context of utterance yet which seems unmarked at the syntactic level.

These types of pragmatic determinant of what is said (i.e., contextually supplied information which is semantically relevant but syntactically unmarked) have come to be known as 'unarticulated constituents' (UCs). Such elements are extremely interesting to philosophers of language since they seem to show that there are problems with a quite standard conception of formal semantics, according to which the route to meaning runs along exclusively syntactic trails.

Now, as noted above, even in formal theories of meaning, like truth-conditional accounts (*see* **Truth Conditional Semantics and Meaning**), some appeal to a context of utterance must be made in order to cope with overtly context-sensitive expressions. However, the thought has been that this need not contravene the essentially formal nature of our theory, since the contextual instructions can be syntactically triggered in this case (crudely, the word 'that' tells us to find a demonstrated object from the context of utterance). Much more problematic, then, are pragmatic determinants of what is said which apparently lack any syntactic basis, for they show that context can come to figure at the semantic level regardless of whether it is syntactically called for (thus there will be no purely syntactic route to meaning).

In response to the challenge posed by UCs, advocates of formal semantics have sought to reject the idea that there are any such things as syntactically unrepresented but semantically relevant elements, claiming either that

1. every contextual element of what is said really is syntactically represented, even though this fact may not be obvious from the surface syntax of a

Abstract:

Recently, the established way of thinking about speech acts (in the tradition of Austin, Searle, Grice, and their followers) has undergone a remarkable change. From being an effort to represent human words in terms of what they 'do' (Austin), or how they can be used to produce 'speech acts' (Searle) or to generate 'implicatures' (Grice), the focus has shifted to the situation in which words are spoken and how this contributes to understanding the utterance, or even how the situation can predefine and to a degree determine what can be said. The upshot of these considerations is that we need a new theory, one that takes into account the inter- and transactional aspects of speech acting. This article proposes such a theory under the label of 'pragmatic acts' – acts that work not just by their wording but also by their being embedded in a situation in which humans act, with everything that humans bring to their interactional forum, including body movements, emotions, and so on.

Biography:

Jacob L Mey (b. 1926) is Professor Emeritus of Linguistics at the University of Southern Denmark. Previous appointments include the University of Oslo, Norway; the University of Texas at Austin; Georgetown University, Washington, DC; Yale University, New Haven, CT; Tsukuba University, Japan; Northwestern University, Evanston, IL; City University of Hong Kong; Goethe University, Frankfurt am Main; Universidade Estadual de Campinas, S.P., Brazil; Universidade de Brasília, Brasília, DF; the University of Haifa and Haifa Technion, Israel; as well as numerous other institutions of research and higher learning. His research interests concern all areas of pragmatics, with an emphasis on the social aspects of language use, the pragmatic impact of computer technologies, and the pragmatic use of literary devices. Among his publications in these areas are *Pragmalinguistics: theory and practice* (Mouton, 1979), *Whose language? A study in linguistic pragmatics* (Benjamins, 1985), and *Pragmatics: an introduction* (Blackwell, 1993; 2nd rev. edn., 2001). His most recent publication is *As Vozes da Sociedade* (*The voices of society;* in Portuguese) (Mercado de Letras, 2002). Regarding the computer-related aspects of pragmatics, a recent development is a new field, cognitive technology (CT), which he is among the first to have developed, having written and edited numerous articles and books in the area and coorganized several international conferences (together with Barbara Gorayska). The main interest of CT is to study the effects of the computer on the human mind and how the mind determines the uses we make of the computer as a tool. Among his other main interests are the theory of literature and poetics. These interests culminated (following many previous articles) in his book *When voices clash: a study in literary pragmatics* (Mouton de Gruyter, 2000). He is founder (with Hartmut Haberland) and chief editor of the monthly *Journal of Pragmatics*. He also edits *RASK: International Journal of Languages and Linguistics*. Among his edited volumes are two readers on cognitive technology (Elsevier Science, 1996 and 1999) and the 1100-page *Concise encyclopedia of pragmatics* (Elsevier Science, 1998). He holds an honorary D.Phil. degree from the University of Zaragoza, Spain. He is a member of various professional organizations, such as the Linguistic Society of America, the Copenhagen Linguistic Circle, and the International Pragmatics Association (of which he is a member of the consultative board). He is editor or member of the advisory board of a number of series and journals, such as *Pragmatics and Beyond* (Amsterdam); *Anthropological Linguistics* (Berlin); *Discourse and Society; Text, Language and Literature* (Liverpool); *Miscelánea* (Zaragoza); *Psyke og Logos* (Copenhagen); *Sémantique et Pragmatique* (Orléans); and *Cadernos de Linguagem e Sociedade* (Brasília).

Imagine that Jack, pointing at a book on the table, utters the sentence "That is better than Jill's book." What, we might ask, is said by his utterance? Well, since the sentence contains a context-sensitive expression – the demonstrative 'that' – we know that determining what is said will require an appeal to the context of utterance to provide a referent (*see* **Indexicality: Theory**). Thus, this is one kind of pragmatic determinant of what is said by Jack's utterance. The sentence is also context sensitive in another, slightly less obvious, way: it is in the present tense, so an appeal to the context of utterance will also be needed to fix a time for Jack's claim. Finally, many theorists recently have argued that the sentence is also context sensitive in a third, much less obvious, way: for to grasp what is said by Jack it seems that we also need to know what kind of relationship he envisages between Jill and her book. Does Jack intend to say that the book he is demonstrating is better than the book Jill wrote, better than the book Jill owns, the book Jill is reading, etc? And what does he mean by 'better' here – better written, better researched, better for standing on to reach a high shelf? Surely Jack says more than merely that the book he is demonstrating is better in some respect or other than a book bearing some relationship or other to Jill, but, if so, then any such additional information can only come from consideration of the context of utterance.

Furthermore – and this is where the current case differs from that of demonstratives and tense – it's not obvious that this last type of pragmatic determinant of what is said is traceable to any overt (i.e., syntactically represented) context-sensitive element. Jack's utterance does contain the syntactically marked possessive, but *'s* certainly doesn't appear on the list of usual suspects for context-sensitive expressions. And in many cases even this degree of syntactic representation is missing. Consider an utterance of "It's raining," where what is said is that it is raining at some location, l, or "You won't die," saying that you won't die from that cut, or "Nietzsche is nicer," meaning that Nietzsche is nicer than Heidegger. Or again, consider the speaker who produces a nonsentential utterance, e.g., pointing at a child and saying "George's brother," thereby conveying that he is George's brother. In all these cases we have additional information contributed by the context of utterance yet which seems unmarked at the syntactic level.

These types of pragmatic determinant of what is said (i.e., contextually supplied information which is semantically relevant but syntactically unmarked) have come to be known as 'unarticulated constituents' (UCs). Such elements are extremely interesting to philosophers of language since they seem to show that there are problems with a quite standard conception of formal semantics, according to which the route to meaning runs along exclusively syntactic trails.

Now, as noted above, even in formal theories of meaning, like truth-conditional accounts (*see* **Truth Conditional Semantics and Meaning**), some appeal to a context of utterance must be made in order to cope with overtly context-sensitive expressions. However, the thought has been that this need not contravene the essentially formal nature of our theory, since the contextual instructions can be syntactically triggered in this case (crudely, the word 'that' tells us to find a demonstrated object from the context of utterance). Much more problematic, then, are pragmatic determinants of what is said which apparently lack any syntactic basis, for they show that context can come to figure at the semantic level regardless of whether it is syntactically called for (thus there will be no purely syntactic route to meaning).

In response to the challenge posed by UCs, advocates of formal semantics have sought to reject the idea that there are any such things as syntactically unrepresented but semantically relevant elements, claiming either that

1. every contextual element of what is said really is syntactically represented, even though this fact may not be obvious from the surface syntax of a

sentence (i.e., there is more to our syntax than initially supposed), or that

2. any contextual contributions which are not syntactically marked are not semantically relevant (i.e., there is less to our semantics than initially supposed).

The first of these moves is pursued by a number of theorists who argue that, if one pays proper attention to all the information given at the syntactic level, one will find that many cases of supposedly syntax-independent semantic contribution are, in fact, syntactically required (see Stanley, 2000; Stanley and Szabo, 2000; Taylor, 2001; Recanati, 2002). Now, that there is some discrepancy between surface form and underlying syntax is a well-rehearsed point. For instance, Russell's theory of descriptions invokes a clear distinction between surface form and logical form. Furthermore cases of so-called syntactic ellipsis (like the contraction in "Jack likes dogs and so does Jill," where the second sentence is held to have the underlying syntactic form "Jill likes dogs" despite its reduced verbal form) show that surface constituents may be poor indicators of syntactic elements. If this is correct, then the principle that there is more to our syntax than is apparent at first glance is independently well motivated.

Given this, there certainly seem to be cases in which (1) is an appealing response to putative examples of UCs. To give an example: someone might claim that, because an utterance of "Jack plays" can be used in one context to say that Jack plays the trombone and in another to say that Jack plays football, there must be a syntactically **un**marked, contextual contribution to the semantic content of an utterance of this kind. However, closer inspection of the syntax shows this conclusion is dubious: 'plays' is a transitive verb requiring a subject and an object and, although the argument place for an object can be left unfilled at the surface level without this making the sentence ill formed, it might be argued that the additional argument place **is** marked in the underlying syntax of the verb. Since 'plays' is a transitive verb, the competent interlocutor will, on hearing "Jack plays," expect to look to a context of utterance to discover what Jack plays, but this is precisely because she is sensitive to the syntactic structure of English in this case. Thus sometimes an appeal to an enriched syntax seems the best way to cope with putative UCs. However, there are also cases where (1) seems less compelling. For instance, in certain contexts, it seems that Jack can use an utterance of "The apple is red" to convey the proposition that the apple is red to degree *n* on its skin. Yet it is far from clear that the correct syntactic structure for color terms includes argument places for the shade, or precise manner of instantiation, of the color. Furthermore, the idea that syntactic structure can outstrip surface form at all (or at least in the ways required by [1]) has been rejected by some.

So, the opponent of UCs might seek to supplement (1) with (2), allowing that some contextually supplied information is not marked at the syntactic level but denying that such information is semantically relevant. The advocate of this kind of response wants to accept that, at an intuitive level, the speaker who utters "The apple is red" (or "You won't die," etc.) clearly does convey the contextually enriched proposition (i.e., that the apple is red on the outside, or that you won't die from that cut) but that this is an instance of speaker meaning rather than semantic ontent (*see* **Semantics–Pragmatics Boundary**). Now, whether this move is warranted in all cases is again something of a moot point. One objection might be that it is a mistake to seek to separate speaker intuitions about what is said and claims of semantic content to the radical degree predicted by this kind of move. So, for instance, it seems that the message recovered from an utterance of "That banana is green" will always be that that banana is green in some salient respect, but if this is the kind of proposition competent speakers can and do recover in communicative exchanges, shouldn't this be what semantics seeks to capture? What role could there be for a more minimal kind of semantic content (e.g., which treats semantic content as exhausted by the proposition that that banana is green *simpliciter*)? (See Borg, 2004; Cappelen and Lepore, 2005, for attempts to answer this question.) A second worry for the formal semanticist who pursues (2) is that it may undermine her claim that semantics deals with complete propositions or truth-evaluable items. For instance, take the situation where the book Jack demonstrates is better than the book Jill is reading, but worse than the book she wrote. To assess Jack's opening utterance as true or false in this situation, it might seem that we need first to determine what relationship Jack intended by his utterance of "Jill's book." Without this pragmatically determined aspect of what is said, it is argued, the sentence Jack produces is simply not truth evaluable, it doesn't express a complete proposition (cf. Recanati, 2003).

Clearly, then, although the formal semanticist can respond to the challenge of UCs with moves like (1) and (2) it is not at all obvious that these responses are sufficient. However, we should also be aware that there are problems to be faced on the other side, by the proponent of UCs, as well. One major worry is how to preserve our intuitive distinction between semantically relevant elements and elements which are only pragmatically relevant. Given the traditional

conception of formal semantics, the answer to this question was clear: something is semantically relevant if it can be traced to the syntax of the sentence, it is pragmatically relevant otherwise. Once we admit of semantically relevant but syntactically unmarked elements, however, this way of characterizing the distinction is clearly unavailable, so the proponent of UCs owes us some other account. If Jack utters "I've eaten" then it might seem plausible to claim that the semantic content of this utterance is that he has eaten breakfast today, but he might also succeed in conveying the messages that he has eaten a cooked breakfast within the last hour, or that he is not hungry, or any number of further propositions. How do we decide which elements come to figure in the supposed semantic content of the utterance, and on what basis do we rule some conveyed messages as merely pragmatic?

A further worry seems to be that, for each additional contextual contribution we introduce, this contribution is itself open to further qualification: an utterance of "That banana is green" might intuitively be contextually enriched to that banana is green on its skin, but why stop here? Does the speaker mean to say that that banana is green all over its skin, that that banana is mostly green on a particular patch of skin, or that that banana is a bit green on this bit of surface skin and to a depth of degree *n* through the skin? The problem is that, for any piece of contextual information we introduce via a UC, this piece of information is itself likely to allow for a number of different contextual qualifications or sharpenings, and we seem to lack any principled reason to disallow these further sharpenings from appearing as part of the semantic content of the utterance. Yet, without such a reason, we run the risk of being launched on a slippery slope whereby the meaning of every utterance turns out to be a proposition which is somehow 'complete' in every respect. Yet no such conclusion seems palatable: it undermines notions of systematicity for meaning and makes it completely unclear how we ever come to learn and use a language given our finite cognitive resources (*see* **Compositionality: Semantic Aspects; Compositionality: Philosophical Aspects; Systematicity**).

So, it seems there are problems on both sides of the debate here and the question of how to handle pragmatic determinants of what is said remains a vexed one. The advocate of formal semantics needs to deliver an account both of overtly context-sensitive expressions – the indexicals, demonstratives, and tense markers of a natural language – and of the more covert kinds of context sensitivity discussed here. Reflecting on the multitude of ways in which a context of utterance can apparently affect issues of linguistic meaning certainly seems to show that the formal semanticist runs the risk of undervaluing the role played by pragmatic determinants in what is said. Yet it remains to be seen whether this constitutes merely a potential oversight on her behalf (cf. Stanley, 2000; Stanley and Szabo, 2000; Borg, 2004) or a fundamental failing of the whole approach (cf. Sperber and Wilson, 1986; Carston, 2002).

Pragmatic Indexing

M Silverstein, The University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Indexicality is just the principle of contextualization of linguistic and other signs-in-use, seen as a component of the meaning of the occurring sign-forms. Indexicality is revealed in the way that, by degrees, linguistic and other signs point the users of these signs to the specific enveloping conditions in which they use them. Signs point to context in two ways: indexical signs link users to contextual conditions of which users have knowledge, independent of the occurrence of the particular indexical sign at issue; indexicals also link users to contextual conditions that, for those users, come into being only as a function of the occurrence of the indexical sign at issue (*see* **Context, Communicative**). For its users, the occurrence of an indexical sign is an event that, like a mathematical function, maps a context configured in a certain way into a context now configured in perhaps another way. Consider an expression, the use of which counts as an insult under particular, already mutually understood conditions. When it is directed as such to an addressee, once emerged in the interpersonal space between two people, its directed occurrence irreversibly transforms social relations so that much interpersonal work – further signs-in-use – might have to be undertaken, and things are never again quite as they were in the *status quo ante*.

The two contextualizing directions of indexicality – presupposing indexicality and creative or entailing indexicality (Silverstein, 1976; 1993) – are not, then, simply converse equivalents. They correspond to the two intuitions that sign users manifest, on the one hand about the 'appropriateness' of their messages to the momentary givens of the context as they understand them, and on the other hand about the performative 'effectiveness' of their messages in bringing about intersubjective consequences in the contexts in which they communicate. For semiotic pragmatists, empirical study of indexicality investigates how actual messages, used on specific occasions of communication, relate to norms of appropriateness and effectiveness implicitly shared by users of the various sign modalities studied (*see* **Pragmatics: Overview**). Are there norms of 'who-can-communicate-what-message-to-whom-about-whom-or-what-under-what-conditions'? Are there norms of 'what-kind-of-act-is-performed-or-event-brought-about-in-the-communication-of-certain-message-forms'? How people use signs in actual event contexts can be interpreted only in relation to such norms; that is, events of how signs occur in their contexts of use can be studied as the medium through which social relationships among actual communicators are established, maintained, and transformed relative to the norms being invoked in actual practice.

Many writers, ancient and modern, have recognized and remarked on essentially this property of signs; the whole field of rhetoric in the Western tradition, we can see retrospectively, has been focused on it (*see* **Rhetoric, Classical**). It was Charles Sanders Peirce (1839–1914) who first systematized the concept of indexicality within a more encompassing framework of the semiotic (sign-based) foundations of all epistemology and ontology (*see* **Peirce, Charles Sanders (1839–1914)**). Of all the grand – and ever unfinished – architectonic of his philosophy, Peirce's specific trichotomous distinction in which indexicality figures has been particularly influential for the analysis of cultural systems such as language. Peirce distinguished among *iconic* sign relationships (signs by resemblance or likeness to their semiotic targets), *indexical* sign relationships (signs of spatiotemporal or other contiguity, including causal connection to another object, to which they point), and *symbolic* signs (implicit sign regularities, depending on general classificatory conventions that any instance of the sign invokes in use).

Many philosophers, logicians, and other students of cognition have considered how natural languages measure up against algorithmic systems invented for formally modeling the (normative, if not actual) coherence of human inferencing (what is sometimes termed 'symbolic logic') (*see* **Inference: Abduction, Induction, Deduction**). All have therefore been obligated to treat the pervasive fact of indexicality in natural languages, as language is the recognized human instrument for referring and predicating (Reichenbach, 1947; Bar-Hillel, 1954). Such accounts have at least recognized referential deixis, the way that objects of reference can be relationally located in respect of the – indexed! – contextual conditions under which an instance of a deictic form is used and to which it therefore points (*see* **Deixis and Anaphora: Pragmatic Approaches**). That is, every human language includes paradigms of grammatical forms (such as French *celui-ci* 'this one [masc.]' and *celui-là* 'that one [masc.]') that locate an object of reference in relation to its position in the (broadly speaking) 'spatial' configuration of the triad sender (speaker)–receiver (addressee)–referent in a communicational situation. In short, the 'sense' – the presumed-upon norm of form-meaning relationship – for such a deictic is a rule for the 'appropriate' use of each instance of the form to pick out a referent that conformingly

co-occurs in the communicative context. All such systems of grammatical deixis impose upon instances of communication a kind of radial topology as a structuring principle, with various elaborations of a basic two-valued distinction ('here'-and-'there' kinds of systems), as in Latin three-valued demonstrative paradigms, and with various generalized usage beyond the merely physical arrangement of an inhabitable speech context (for example, using deictics also to track the order of introduction of referents in the grammaticized topological flow of temporally unfolding discourse; cf. English *former* vs. *latter*).

Roman Jakobson (1896–1982), Emile Benveniste (1902–1976), and Jerzy Kuryłowicz (1895–1978), however, among linguists, saw the pervasive role of indexicality in every natural language, far beyond mere deictic reference. The notion that every structure of what Saussure termed *langue*, or Chomsky termed 'competence,' was formally pervaded and functionally framed by Saussurean *parole*, or by Chomskyan 'performance,' was developed in Jakobson's seminal *samizdat* of the annus mirabilis 1957, entitled *Shifters, verbal categories, and the Russian verb* (Jakobson, 1971), in Benveniste's series of papers of the same period, reprinted in his *Problèmes de linguistique générale* (1966, 1971), and in Kuryłowicz's generalizations from historical morphosyntactic studies of the Indo-European languages, beginning with his theories of 'derivation' (1936) and culminating in his *Inflectional categories of Indo-European* (1964; cf. 1960, 1972) (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913); Chomsky, Noam (b. 1928); Kuryłowicz, Jerzy (1895–1978); Jakobson, Roman (1896–1982)**). At once, matters of context and its configuration came into view in the grammatical analysis of how people achieve even the simplest of communications in the way of grammatically formed referring and predicating: relying systematically on the minutest processing of details of context, such as role relationships of speakers, addressees, audiences, and referents, as manifested in categories of 'person'; on presumptions of prior communicational events underlying warrants for speaking, as is manifested in categories of 'evidentiality'; on differentiation of interests of speaker and addressee in the events being narrated, as manifested in the 'epistemic' differentiation of two planes of tense systems; and so forth. Peirce's concept of indexicality was, then, generalizable beyond deictic reference as such to encompass the essentially context-dependent, context-suffused character of all linguistic communication and, more importantly, of anything one might term the structural norms for the referential and predicational use of verbal signs.

In this light, it becomes clear that as modern linguistic anthropology developed by phases through an 'ethnography of speaking' (or 'of communication') (Gumperz and Hymes, 1964, 1972; Hymes, 1974; Gumperz, 1982), its concerns for the sociocultural contextualization of language use were the same as those of these European theorists of a *linguistique de la parole* (*see* **Linguistic Anthropology**). Similarly, the studies of social interaction following on the Chicago School symbolic interactionism within the discipline of sociology – Goffman's (1967, 1969, 1974, 1981), those of ethnomethodology (Garfinkel, 1967; Cicourel, 1974), and conversation analysis (Sudnow, 1972; Levinson, 1983; Duranti and Goodwin, 1992) – are readings of the flow of interactional events achieved in the course of interpersonal co-participation in linguistically mediated communication (*see* **Ethnomethodology; Conversation Analysis; Goffman, Erving (1922–1982); Interactional Sociolinguistics**). Intellectually, if not disciplinarily, it remained only to bring together all these interests to the study of actual language forms through the concept of the pervasive indexicality of the linguistic sign, and to understand the indexicality of language and its perilinguistic semiotic modes in terms congenial to the social and cultural analysis of situations of communication.

By so doing, contemporary linguistic anthropology (see Duranti, 2001, 2004; Silverstein and Urban, 1996) has been centered on the analysis of indexicality in every aspect of semiotic codes in use, and particularly of language: how does the flow of discourse, as it comes to cohesive textual form, indexically construe and construct relevant sociocultural framings of its producers (speakers, addressees, audiences, even analysts) and its denoted characters? Such framings are on the order of shared, or at least sharable, schematizations of identity (kinds of persons), of discourse genre (kinds of social occasions and events), of institutional space (kinds of allocated realms of access), and so forth. In the course of using language and such, communicative interlocutors locate themselves and others in such framings; the very forms they use among a language community's varied possibilities indexically project these framings as the understood conceptual surround of the current communication, making them relevant to its course and outcome. The way that the personnel of social interaction, as we might term them, come to be projectively located or positioned is a central part of the work of communication. Once they are so located, what goes on in the way of moving participants to new relative social locations, or of adding further, concurrent social locations to ones already presupposed, constitutes the dynamic indexical work

of conversation. It is in this sense that much of the work of social identity is achieved and clarified in conversation, making it seem that aspects of social personae, like gender, class, and ethnicity, are 'performed.' When we view the matter as one of social indexicality, however, the real issue is not the normative existence of schemata of social classification, so much as the indexical clarity – in terms of directness vs. indirectness of indexation, ambiguousness vs. discernibility, congruence vs. contradictoriness, etc. – with which particular individuals in particular kinds of interactional events come to be consequentially positioned in one or more of these frameworks. (For example, on gender as 'performed' in relation to other aspects of relational identities, see Silverstein (1985), Ochs (1992), Kiesling (2001a,b), Cameron and Kulick (2003), Eckert and McConnell-Ginet (2003), Bucholtz and Hall (2004), and Hastings and Manning (2004)).

Indeed, to a great extent, interactional moves seemingly concerned with denotational content, such as taking a contrary stand on something predicated by a conversational partner, or agreeing with the interlocutor while transforming the denoting terms of what seems to be agreed upon, are not really concerned with denotational content, or are concerned with it only residually. Rather, as conversational moves doing interactional work, such discursive contributions dynamically index what is going on; they figurate in the medium of denotational content acts of self/other repositioning within a relevant cultural framework indexically rendered 'in play' at such a point in interaction. In this way, 'other-mindedness' in respect of explicitly denoted content comes to count, implicitly and interactionally, as mutual counter-alignment of communicative participants in a social sense in a framework of identities and interests, whether momentary or with more perduring consequences of symmetric or asymmetric exclusion. All this social work, moreover, is generally accomplished only indexically, that is, entirely implicitly, and can therefore go officially unnoticed – it can even be plausibly denied – by participants, even if it materializes to indexical interpretation under the analytic lens of the student of interactional events.

Pragmatic Presupposition

C Caffi, Genoa University, Genoa, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Both concepts – 'pragmatic' and 'presupposition' – can be interpreted in different ways. On the one hand, not being very remote from the intuitive, pretheoretical concept of presupposition as 'background assumption,' the concept of presupposition covers a wide range of heterogeneous phenomena (*see* **Presupposition**). Owing to the principle of communicative economy as balanced by the principle of clarity (Horn, 1984), in discourse much is left unsaid or taken for granted.

In order to clarify the concept of presupposition, some authors have compared speech with a *Gestalt* picture in which it is possible to distinguish a ground and a figure. Presuppositions are the ground; what is actually said is the figure. As in a *Gestalt* picture, ground and figure are simultaneous in speech; unlike the two possible representations in the *Gestalt* picture, speech ground and figure have a different status, for instance with respect to possible refutation. What is said, i.e., the figure, is open to objection; what is assumed, i.e., the ground, is "shielded from challenge" (Givón, 1982: 101). What crucially restricts the analogy is the fact that discourse is a dynamic process, whereas a picture is not. At the same time that an explicit communication is conveyed in the ongoing discourse, an intertwined level of implicit communication is unfolding: understanding a discourse requires an understanding of both. When communicating, we are constantly asked to choose what to put in the foreground and what in the background. Discourses and texts are multilevel constructs, and presuppositions represent (at least a part of) the unsaid (*see* **Pragmatics: Overview**).

On the other hand, the label 'pragmatic' can be used in different ways. It may refer, first, to a number of objects of study and, second, to a number of methods of analysis linked by the fact that they take into account elements of the actual context (*see* **Pragmatics: Overview**; **Metapragmatics**; **Pragmatic Indexing**; **Indexicality: Theory**). What is called 'pragmatic' may in fact be an expanded semantic object (*see* **Semantics–Pragmatics Boundary**). Generally speaking, a requirement for a truly pragmatic treatment seems to be that it is concerned more with real usages of language(s) than with highly abstract models dealing with oversimplified, construed examples. Ultimately, "what I can imply or infer, given a presupposition, depends on an active choice made in the face-to-face confrontation with my interlocutor" (Mey, 2001: 29).

The origin of the concept of pragmatic presupposition must be sought in the recognition by philosophers of language and logicians that there are *implicata* of utterances that do not belong to the set of truth conditions (*see* **Truth Conditional Semantics and Meaning**). Their starting point is the awareness that there are other relations between utterances besides that of entailment.

The definitions of pragmatic presupposition proposed in the 1970s have brought about a pragmatic rereading of a problem that was above all logical and that had not found adequate explanation in the

Pragmatic Presupposition

Introduction

Both concepts – 'pragmatic' and 'presupposition' – can be interpreted in different ways. On the one hand, not being very remote from the intuitive, pretheoretical concept of presupposition as 'background assumption,' the concept of presupposition covers a wide range of heterogeneous phenomena (*see* **Presupposition**). Owing to the principle of communicative economy as balanced by the principle of clarity (Horn, 1984), in discourse much is left unsaid or taken for granted.

In order to clarify the concept of presupposition, some authors have compared speech with a *Gestalt* picture in which it is possible to distinguish a ground and a figure. Presuppositions are the ground; what is actually said is the figure. As in a *Gestalt* picture, ground and figure are simultaneous in speech; unlike the two possible representations in the *Gestalt* picture, speech ground and figure have a different status, for instance with respect to possible refutation. What is said, i.e., the figure, is open to objection; what is assumed, i.e., the ground, is "shielded from challenge" (Givón, 1982: 101). What crucially restricts the analogy is the fact that discourse is a dynamic process, whereas a picture is not. At the same time that an explicit communication is conveyed in the ongoing discourse, an intertwined level of implicit communication is unfolding: understanding a discourse requires an understanding of both. When communicating, we are constantly asked to choose what to put in the foreground and what in the background. Discourses and texts are multilevel constructs, and presuppositions represent (at least a part of) the unsaid (*see* **Pragmatics: Overview**).

On the other hand, the label 'pragmatic' can be used in different ways. It may refer, first, to a number of objects of study and, second, to a number of methods of analysis linked by the fact that they take into account elements of the actual context (*see* **Pragmatics: Overview**; **Metapragmatics**; **Pragmatic Indexing**; **Indexicality: Theory**). What is called 'pragmatic' may in fact be an expanded semantic object (*see* **Semantics–Pragmatics Boundary**). Generally speaking, a requirement for a truly pragmatic treatment seems to be that it is concerned more with real usages of language(s) than with highly abstract models dealing with oversimplified, construed examples. Ultimately, "what I can imply or infer, given a presupposition, depends on an active choice made in the face-to-face confrontation with my interlocutor" (Mey, 2001: 29).

The origin of the concept of pragmatic presupposition must be sought in the recognition by philosophers of language and logicians that there are *implicata* of utterances that do not belong to the set of truth conditions (*see* **Truth Conditional Semantics and Meaning**). Their starting point is the awareness that there are other relations between utterances besides that of entailment.

The definitions of pragmatic presupposition proposed in the 1970s have brought about a pragmatic rereading of a problem that was above all logical and that had not found adequate explanation in the

available semantic theories. This rereading was basically methodological (*see* **Semantics–Pragmatics Boundary**; **Pragmatics and Semantics**).

From Stalnaker's definition (1970) onward, a pragmatic presupposition was no longer considered a relation between utterances but rather was considered one between a speaker and a proposition (*see* **Propositions**). This is a good starting point, but it is far from satisfactory if the label 'pragmatic' is meant to cover more than 'semantic and idealized contextual features,' i.e., if we adopt a radical pragmatic standpoint.

Let us provisionally define a pragmatic presupposition as a '*ménage à trois*' between a speaker, the framework of his/her utterance, and an addressee. From a radical pragmatic standpoint, a substantivist view of presuppositions – i.e., what the presupposition of an utterance is – is less promising than a functional, dynamic, interactional, contractual-negotiating view; the question here is how presupposition works in a communicative exchange. The pragmatic presupposition can be considered as an agreement between speakers. In this vein, Ducrot proposed a juridical definition whereby the basic function of presuppositions is to "establish a frame for further discourse" (1972: 94; my translation). Presuppositions are based on a mutual, tacit agreement that has not been given before and that is constantly renewed (or, as the case may be, revoked) during interaction. Presuppositions are grounded on complicity.

Having been the focus of lively discussions by linguists and philosophers of language during the 1970s, presuppositions seem now to have gone out of fashion. At the time, the "wars of presupposition" (Levinson, 2000: 397) were fought between partisans of a semantic vs. a pragmatic view on the phenomenon. Another war is presently being fought with regard to another – though adjacent – territory, that of the intermediate categories covering the conceptual space between presupposition and implicature (*see* **Implicature**). The fight involves the overall organization of the different layers of meaning (and their interplay); it could be labeled the 'war of (generalized) conversational implicature,' if the latter term were neutral, rather than being the banner of the faction representing one side of the debate, namely the post-Gricean theorists (eminently, though not exclusively, represented by Levinson [2000]). The other side counts among its representatives, first of all, the relevance theorists, as represented by Carston (2002), who advance an alternative concept, called 'explicature,' that is intended to bridge the notions of encoded meaning and inferred meaning (*see* **Relevance Theory**; **Implicature**).

On the whole, the decline of the interest in presupposition as such can be understood, and partly justified, inasmuch as subtler distinctions between the different phenomena have been suggested, and a descriptively adequate typology of *implicata* is in the process of being built (see Sbisà, 1999b). The decline is less justified if the substitution is only terminological, that is, if the intuitive concept of presupposition is replaced by a gamut of theory-dependent concepts without offering any increase in explanatory power with respect to authentic data. In the latter case, it is not clear what advantages might result from the replacement of the umbrella term 'presupposition' by some other, more modish terminology. The point is, once again, the meaning we assign to the word 'pragmatic' and the object we make it refer to: either the rarefied world of construed examples or the real world, where people constantly presuppose certain things in order to reach certain goals.

Once it is clear that a radical pragmatic approach to the issue necessarily takes only the latter into consideration, the question is whether the term 'presupposition' refers to a range of heterogeneous phenomena or, on the contrary, to a particular type of *implicatum*, to which other types can be added. But even before that, we should ask whether, between the established notion of semantic presupposition and the Gricean notion of implicature (which, despite its popularity, still is under scrutiny by both philosophers and linguists), there is room for a concept like pragmatic presupposition. To answer this question, we need to say a few words on how pragmatic presupposition is distinct from the two types of adjacent *implicata* mentioned earlier: semantic presupposition and implicature.

Relation with Semantic Presupposition

The concept of semantic presupposition is relatively clear. Its parentage is accredited: Frege (*see* **Frege, Gottlob (1848–1925)** (01250)), Russell (*see* **Russell, Bertrand (1872–1970)**), Strawson (*see* **Strawson, Peter Frederick (b. 1919)**). Its lineage seems to be traceable back to Xenophanes, quoted in Aristotle's *Rhetoric* (*see* **Rhetoric, Classical**), via Port-Royal (*see* **Port-Royal Tradition of Grammar**) and Stuart Mill (*see* **Mill, John Stuart (1806–1873)**). There is substantial agreement as to its definition: the presupposition of a sentence is what remains valid even if the sentence is denied; its truth is a necessary condition for a declarative sentence to have a truth value or to be used in order to make a statement. A respectable test has been devised to identify it – the negation test. There is a list of the linguistic facts (Levinson, 1983: 181–185) that trigger the phenomenon of presupposition: thirty-one have been listed, from factive verbs

(e.g., *know*, *regret*; *see* **Factivity**) to change-of-state verbs (e.g., *stop*, *arrive*), to cleft sentences (*see* **Clefting in Spoken Discourse**).

The notions of semantic presupposition and conventional implicature (*see* **Maxims and Flouting**), as identified by Grice (who exemplified the latter with *therefore*), can be unified to a certain degree, as both depend on a surface linguistic element that releases the presupposition. The difference between semantic presuppositions and conventional implicatures is that the latter, unlike the former, are irrelevant with respect to truth conditions (*see* **Semantics–Pragmatics Boundary**). In contrast, unlike semantic presuppositions and some conventional implicatures, pragmatic presuppositions are not directly linked to the lexicon, to the syntax, or to prosodic facts (e.g., the contrastive accent in 'MARY has come'; *see* **Intonation**) but are linked to the *utterance act* (*see* **Pragmatic Acts**).

We should distinguish types of *implicata* that are recorded by dictionaries and that either are part of the semantic representation of a lexeme (*see* **Lexeme-Morpheme-Based Morphology**) or are conveyed by given syntactic or prosodic structures, from *implicata* that are independent of both dictionary and grammar: in particular, pragmatic presuppositions are triggered by the utterance and the speech act involved. They are presuppositions neither of a lexeme nor of a proposition nor of a sentence. They are presuppositions that a speaker activates through the utterance, the speech act, and the conversational or textual moves that a given speech act performs. Thus, pragmatic presuppositions concern not imperative *sentences* but orders; not declarative *sentences* but assertions; and so on. In other words, one ought to stress once more the distinction between syntactic and pragmatic functions: between them there is no one-to-one correspondence (see Lyons, 1977). The same linguistic structure, the same utterance, can perform different functions, convey different speech acts, and refer to different sets of presuppositions (*see* **Mood and Modality in Grammar**; **Pragmatics and Semantics**). The acknowledgment of a level of theorizing that goes beyond the sentence is the *sine qua non* for the analysis of pragmatic presuppositions. Pragmatic presuppositions are related to knowledge that is not grammatical but encyclopedic, that is, knowledge that concerns our being in the world (*see* **Metapragmatics**). Or, rather, they consist not in knowledge, in something that is already known, but in something that is *given as such* by the speaker, in something that is *assumed as such* and is therefore *considered irrefutable* (Van der Auwera, 1979).

Once we have recognized the semantic nature of lexical and grammatical (syntactic and prosodic) presuppositions, we should stress the connection between semantic and pragmatic presuppositions. First, the connection is of a general nature and concerns the obvious (but by no means negligible) fact that, when we are dealing not with abstractions but with real utterances, the phenomenon of semantic presuppositions becomes one of the available means by which the speaker can change the communicative situation (*see* **Communicative Principle and Communication**). If the link between, for instance, a certain lexeme and the presupposition it triggers is semantic, their analysis within an utterance and a context must face the pragmatic problem of their use and effects.

Second, on closer examination, this connection is bound up with the specific pragmatic functions performed by phenomena that can be labeled as *semantic* presuppositions. For instance, it is important to recognize the effectiveness of semantic *implicata* (lexical presuppositions, conventional implicatures, presuppositions linked to syntactic constructions such as cleft sentences, etc.,) both in the construction of texts and in the pragmatic strategies of manipulation of beliefs, or, to use Halliday's categories, both in the textual function and in the interpersonal one (*see* **Systemic Theory**; **Halliday, Michael A. K. (b. 1925)**). On the one hand, the analysis of the different types of anaphora and their functioning whenever their antecedent is not what the preceding text stated but what it presupposed, has both textual and pragmatic relevance. On the other hand, precisely because it is shielded from challenge, communication *via* presuppositions lends itself to manipulatory purposes (see Sbisà, 1999a): suffice it to compare the different persuasive effects of an assertion embedded in a factive verb (*see* **Factivity**) vs. a simple assertion (e.g., "People know that solar energy is wishful thinking" vs. "Solar energy is wishful thinking"). Having defined the semantic nature of the different types of presuppositional triggers, we should then recognize the role of pragmatics in the study of the production and interpretation of these potentially highly manipulatory *implicata*. Obviously, it is more difficult to question something that is communicated only implicitly rather than to attack something that is communicated openly, if only because what is implicit must be recognized before it can be attacked. This is attested by the highly polemical and aggressive value inherent in attacks on presuppositions; such moves always represent a serious threat for 'face' (*see* **Face**; **Mitigation**).

Relation with Conversational Implicature

The criteria put forward by Grice to distinguish conversational implicature (*see* **Cooperative Principle**; **Grice, Herbert Paul (1913–1988)**) from other *implicata* (i.e., calculability, nondetachability,

nonconventionality, indeterminacy, cancelability) have not proven to be entirely satisfactory, even when integrated with the further criterion of 'reinforceability' (Horn, 1991). In particular, the criterion of cancelability, viewed as crucial by many authors, seems to be problematic (for a discussion, see Levinson, 1983). And in any case, cancelability is linked to the degree of formality of the interaction: in unplanned speech, it is easily tolerated.

If we are satisfied with an intuitive differentiation that nevertheless uses these criteria, we can reasonably maintain that pragmatic presuppositions are oriented, retroactively, toward a background of beliefs assumed to be shared. Implicatures, on the other hand, are oriented, proactively, toward knowledge yet to be built. Besides (at least if we prototypically think of *particularized* conversational implicatures, i.e., the kind that, according to Grice, strictly depends on the actual context; see Levinson, 2000: 16), such knowledge does not necessarily have to be valid beyond the real communicative situation. Thus, in order to distinguish the two types of *implicata*, the criteria of different conventionality (presuppositions being more conventional than implicatures) and of different validity (the latter being more general in the case of presuppositions, more contingent in the case of implicatures) are called into play. Presuppositions concern beliefs constituting the background of communication. They become the object of communication (thus losing their status of presupposition) only if something goes wrong, if the addressee does not accept them or questions them, forcing the speaker to put his or her cards on the table. Implicatures, on the contrary, concern a 'knowledge' that is not yet shared and that will become such only if the addressee goes through the correct inferences while interpreting the speaker's communicative intention (*see* **Intention and Semantics**). The distinction is thus more a matter of degree than a true dichotomy, the latter, more than the former, requiring the addressee to abandon his or her laziness – the "principle of inertia," as Van der Auwera (1979) called it, i.e., the speaker's reliance on shared beliefs – and to cooperate creatively with the discourse. With implicatures, a higher degree of cooperation and involvement is asked of the addressee (the more I am emotionally involved, the more I am willing to carry out inferential work) (see Arndt and Janney, 1987; *see* **Cooperative Principle**). Presuppositions can remain in the background of communication and even go unconsidered by the addressee without making the communication suffer. Implicatures must be calculated for communication to proceed in the direction desired by the speaker.

The roles of presuppositions and implicatures, seen against the backdrop of the speaker's expectations and the discourse design, are therefore different; the former are oriented toward the already constructed (or given as such), the latter toward the yet to be constructed or, even better, toward a 'construction in progress': the former concern a set of assumptions, the latter their updating.

Presuppositions are more closely linked to what is actually said, to the surface structure of the utterance; implicatures are more closely linked to what is actually meant. Their respective degrees of cancelability also seem to be different: presuppositions are less cancelable than implicatures. This difference between presuppositions and implicatures with respect to the criterion of cancelability could be reformulated in terms of utterance responsibilities and commitment. With presuppositions and implicatures, the speaker is committed to different degrees – more with the former, less with the latter – with respect to his or her own *implicata*. Thus, a definition of pragmatic presuppositions could be formulated as 'that which our hearer is entitled to believe on the basis of our words.' In the case of presuppositions, this implicit commitment is stronger, and so, too, is the sanction, should the presupposition prove to be groundless. And the reason is that in the case of presuppositions, an attempt to perform a given speech act has been made: the linguistic devices have traced out, however implicitly, a detectable direction. The addressee is authorized to believe that the speaker's speech act was founded, i.e., that his or her own presuppositions were satisfied. A character in Schnitzler's *Spiel im Morgengrauen* implacably says to the second lieutenant who has lost a huge amount of money playing cards with him and does not know how to pay his debt: "Since you sat down at the card-table you must obviously have been ready to lose." Communicating is somehow like sitting down at the card table: presuppositions can be a bluff.

The Gricean concept of implicature can be compared to Austin's concept of perlocution (*see* **Speech Acts; Speech Acts: Definition and Classification; Austin, John Langshaw (1911–1960)**), with which it shares the feature of nonconventionality: implicature is an actualized perlocution. From the utterance 'My car broke down,' I can draw a limited number of presuppositions, e.g., 'there's a car,' 'the car is mine,' 'the car was working before,' but an indefinite number of implicatures, e.g., 'Where's the nearest garage?,' 'I can't drive you to the gym,' 'Can you lend me some money to have it repaired?,' 'Bad luck haunts me.'

Finally, an interesting relationship is the symbiosis of pragmatic presuppositions and implicatures in indirect speech acts (*see* **Speech Acts; Pragmatic Acts**): the presuppositions of the act

(preparatory conditions in particular) are stated or questioned so as to release a (generalized conversational) implicature (*see* **Implicature**).

Pragmatic Presuppositions: 'Classical' Definitions

Officially, at least, pragmatic presuppositions have had a short life. The available registry data on pragmatic presuppositions reveal the following: born 1970 (Stalnaker); died (and celebrated with a requiem) 1977 (Karttunen and Peters). The two latter authors proposed to articulate the concept of presupposition into (a) particularized conversational implicatures (e.g., subjunctive conditionals, *see* **Conditionals**), (b) generalized conversational implicatures (e.g., verbs of judgment), (c) preparatory conditions on the felicity of the utterance, (d) conventional implicatures (e.g., factives, *even*, *only*, *but*). The reader edited by Oh and Dinneen (1979) can also be seen as a *post mortem* commemoration.

Against the backdrop of the inadequacies of the concept of semantic presupposition, Stalnaker (1970: 281) introduced the concept of pragmatic presupposition as one of the major factors of the context. Pragmatic presupposition enabled him to distinguish contexts from possible worlds; it was defined as a "propositional attitude" (*see* **Context, Communicative**). In the same paper, Stalnaker (1970: 279) also said that the best way to look at pragmatic presuppositions was as "complex dispositions which are manifested in linguistic behavior." Confirming the equivalence between pragmatic presupposition and propositional attitude (*see* **Propositions**), Stalnaker (1973: 448) defined pragmatic presupposition in the following way: "A speaker pragmatically presupposes that B at a given moment in a conversation just in case he is disposed to act, in his linguistic behavior, as if he takes the truth of B for granted, and as if he assumes that his audience recognizes that he is doing so." Stalnaker's definition showed a tension between the definition of pragmatic presupposition on the one hand as a disposition to act and on the other as a propositional attitude: pragmatic terms and concepts, such as 'disposition to act' and 'linguistic behavior,' were used alongside with semantic terms and concepts, 'the truth of B' in particular. In Stalnaker's treatment (1970: 277–279), a narrow meaning of the concept of 'pragmatic' was associated with an extended meaning of the concept of 'proposition,' which was the object both of illocutionary and of propositional acts. This tension is still present and verges on a clash in Stalnaker (2002), where the most distinctive feature of the propositional attitude (which, according to Stalnaker, was constitutive of a presupposition) was defined as a "social or public attitude" (2002: 701).

Keenan, distinguishing between logical and pragmatic notions, defined pragmatic presupposition as a relation between "utterances and their contexts" (1971: 51): "An utterance of a sentence pragmatically presupposes that its context is appropriate" (1971: 49) (*see* **Context, Communicative; Context Principle**). In an almost specular opposition to Stalnaker, Keenan seemed to extend his view of pragmatics until it almost coincided with "conventions of usage," as Ebert (1973: 435) remarked. At the same time, Keenan also seemed to hold a restricted view of the phenomenon of 'presupposition,' as exemplified by expressions that presuppose that the speaker/hearer is a man/woman (sex and relative age of the speaker/hearer), by deictic particles referring to the physical setting of the utterance and by expressions indicating personal and status relations among participants (e.g., French '*Tu es dégoûtant*', literally, 'You [informal] are disgusting [male]').

Among other interesting definitions, there is the following one, offered by Levinson (1983: 205): "an utterance A *pragmatically presupposes* a proposition B iff A is *appropriate* only if B is *mutually known* by participants."

Givón's definition (1982: 100) articulated the prerequisite of mutual knowledge (*see* **Shared Knowledge**) more clearly: "The speaker assumes that a proposition **p** is *familiar* to the hearer, likely to be *believed* by the hearer, *accessible* to the hearer, within the reach of the hearer etc. *on whatever grounds*."

Some conclusions are already possible. In particular:

1. The two definitions of presupposition as semantic and pragmatic (Stalnaker) or as logical and discursive (Givón, 1982) are compatible (cf. Stalnaker, 1970: 279).
2. Logical presupposition is a subcase of discursive presupposition: "logical presupposition is [. . .] the marked sub-case of discourse backgroundedness" (Givón, 1984: 328).

One element occurs with particular frequency in the definitions – it is that of presupposition as 'common ground.' Here, the preliminary move from presupposition as propositional attitude to presupposition as shared knowledge (*see* **Shared Knowledge**), from the world of utterances to the world '*en plein air*,' was Stalnaker's (1973).

Now, both the narrow definition (presupposition as propositional attitude) and the extended one (presupposition as shared belief) involve a high degree of idealization. We are entitled to ask: What is common ground? What is shared knowledge? Is there a

different 'common ground' for different communities of speakers? And to what extent and on the basis of what kind of conjecture, even within the same community, can we speak of 'common ground'? Stalnaker (1974) realized the Platonic flavor of this notion when he gave examples of asymmetry in 'shared knowledge' (such as in his imagined conversation with one's barber). According to Stalnaker, defining presupposition in terms of common knowledge worked "[i]n normal, straightforward serious conversational contexts where the overriding purpose of the conversation is to exchange information [...] The difficulties [...] come with contexts in which other interests besides communication are being served by the conversation" (1974: 201). But what are the criteria that define a conversation as 'normal,' 'straightforward,' and 'serious'? Further, are there no other interests in play beyond those of exchanging information (such as are present in *every* conversation)?

Finally, it is worthwhile stressing that the concept of 'common ground' is effective only as a '*de jure*,' not as a '*de re*,' concept, i.e., not as something ontologically stated but as something deontically given (*see* **Modal Logic**) by the speaker (Ducrot, 1972); that is, it represents a frame of reference that the hearer is expected to accept. On the one hand, a field of anthropological, sociological, and rhetorical investigation opens up before us. On the other hand, the characterization of presupposition as shared knowledge risks being static and idealizing and contains a high amount of ideological birdlime (*see* **Anthropology and Pragmatics**; **Context, Communicative**).

Pragmatic Presuppositions as Felicity Conditions

At this point, a few further remarks are in order. First of all, the classic presuppositional model is *semantic*; even when a notion of pragmatic presupposition is invoked, what is in fact presented is no more than an analysis of some semantic phenomena. Pragmatic notions such as that of 'utterance' or 'context' (*see* **Context, Communicative**; **Context Principle**) are invoked with the main aim of avoiding the contradictions inherent in purely semantic models. The most refined treatment of pragmatic presupposition, by Gazdar (1979), did not escape this kind of contradiction. Second, an assertive model underlies the different definitions of pragmatic presupposition. A point of view centered on truth value is lurking behind allegedly pragmatic presuppositions: the concept of proposition (*see* **Propositions**) (content of an assertion, whether true or false) is the relevant theoretical unit of measurement here. But can this theoretical construct work also as the pragmatic unit of measure? In particular, can this construct adequately deal with communicative behavior? Nothing seems to escape the tyranny of propositions, from the content of the actual utterance to mental content (which, if not presented in propositional form, assumes that shape after being embedded in a predicate like 'know' or 'believe'), to a common or shared knowledge, and to the representation that a logician or a philosopher gives of that content. To what extent is the concept of proposition adequate here? Pragmatic presuppositions concern not only knowledge, whether true or false; they also concern expectations, desires, interests, claims, attitudes toward the world, fears, and so on. The exclusive use of the concept of 'proposition' is idealizing and in the long run misleading, especially when it gives rise to the restoration of the dimension of truth/falsehood as the only dimension of assessing an utterance, whereas this dimension is only one among many possible ones (*see* **Speech Acts: Definition and Classification**).

Neither is the pragmatic level homogeneous with respect to the other levels of linguistic description, such as syntax or semantics; it triggers other questions and anxieties. Pragmatic presuppositions are not a necessary condition to the truth or the falsehood of an utterance; rather, they are necessary to guarantee the felicity of an act.

Once we have abandoned the logico-semantic level of analysis, that is, once we have decided to consider the data of the real communication as our main object, the fact that Oedipus has killed his father is – prior to being an entailment or a presupposition of "*Oedipus regrets having killed his father*" – a shared knowledge common to a particular (Western) culture. "Perched over the pragmatic abyss" (Givón, 1982: 111), we feel giddy. Pragmatic presupposition could actually be God, or the autonomy of cats (of course, excepting the logicians' cats, who, as is well known, invariably remain on their mats). But here the notion of presupposition is being spread so thinly as to run the risk of becoming useless. There is, though, a narrower and more technical meaning of pragmatic presupposition that may help us build a protective wall at the edge of the abyss: it is that of pragmatic presuppositions as the felicity conditions of an illocutionary act.

Let us assume that the relevant unit for the concept of pragmatic presupposition is not the sentence nor the utterance, but the speech act in its entirety (*see* **Speech Acts and Grammar**). Pragmatic presuppositions can be regarded as felicity conditions or, if we adopt Searle's model, as constitutive rules (*see* **Principles and Rules**) of conventional speech acts (e.g., promises, requests, assertions). If a presupposition functioning as a felicity

condition of the act does not hold, the act fails. (Note, incidentally, that a failure of a presupposition has different consequences with respect to a failure of an implicature; in fact, the failure of the latter has no bearing on the success or failure of the illocutionary act).

The identification of presuppositions with felicity conditions is not a new idea: "By the presuppositional aspect of a speech communication," argued Fillmore (1971: 276), "I mean those conditions which must be satisfied in order for a particular illocutionary act to be effectively performed in saying particular sentences. Of course, we need not be concerned with the totality of such conditions, but only with those that can be related to facts about the linguistic structure of sentences." For a pragmaticist, this definition is attractive in that it underscores the need to research systematic relations between utterance function and form. However, it cannot be accepted to the extent that felicity conditions necessarily are of a heterogeneous nature (*pace* Katz, 1977), in that they involve the extralinguistic world; in other words, they concern the place where language and world meet – the communicative situation.

Toward a Pragmatic Definition of Pragmatic Presupposition

A philosophical approach to the problem of linguistic action, seen as a kind of social action, was represented by Austin's typology of infelicities (1962). This was a step forward with respect to undifferentiated notions, such as that of 'appropriateness,' often used in the definition of pragmatic presupposition. Austin's typology helped distinguish between presuppositions without which the act is simply not performed (e.g., in promising somebody something that we do not have) and presuppositions that, if unsatisfied, make the act unhappy (e.g., in promising something insincerely). There are presuppositions whose satisfaction can be seen in binary terms; in other cases, satisfaction occurs according to a scale, in the sense that the presuppositions can be more or less satisfied: the latter cases are the ones concerning the appropriateness of an act on which it is possible to negotiate (an order, however insolent, has been given; advice, although from an unauthoritative source, has been put forward, etc.). The role of nonverbal communication in the successful performance of acts has to a large extent still to be investigated: e.g., if someone offers me congratulations on my promotion, displaying a sad, long face, can I still say he or she is congratulating me (*see* **Gestures: Pragmatic Aspects**)?

In any case, the different types of infelicity help recall the substantial homogeneity of linguistic action to action: pragmatics must be connected to praxeology, to the study of actions as effective or ineffective, even before they can be considered true or false, appropriate or inappropriate (*see* **Pragmatic Acts**).

A decisive move in analyzing pragmatic presuppositions is that of connecting the typology of infelicities to empirical research on the functioning of linguistic and nonlinguistic interaction. For example, in conversation the typology can be related to the various mechanisms of repairs or, more generally, to research on misunderstandings in dialogue (for a survey, see Dascal [ed.], 1999) and on pathological communication (*see* **Psychoanalysis and Language; Conversation Analysis**). To achieve this more dynamic view of pragmatic presuppositions, it is crucial to consider presuppositions not only as preconditions of the act (e.g., as done by Karttunen and Peters, 1977) but also as effects: if the presupposition is not challenged, it takes effect retroactively. If you do not react against my order, you acknowledge my power; if you follow my advice, you accept me as an expert who knows what is best for you; if you do not question my assessment, you ascribe a competence to me (see, among others, Ducrot, 1972: 96–97).

The analysis of *implicata* still requires much theoretical and applied work. Some steps may be sketched out as follows. We can imagine the *implicata* of which pragmatic presuppositions are part, as types of commitments assumed by the speaker in different degrees and ways. The different degrees of cancelability according to which the types of *implicata* have been traditionally classified are related to a stronger or weaker communicative commitment: the speaker is responsible for the *implicata* conveyed by his or her linguistic act; if the addressee does not raise any objection, he or she becomes co-responsible for it. A decisive step is that of leaving behind the truth-functional heritage: rather than recognizing a presupposition as true, the issue is whether or not to accept it as valid.

In a pragmatic analysis of pragmatic presuppositions, it is furthermore necessary to consider the following dimensions:

1. *Sequential-textual and rhetorical* (Eco, 1990: 225). Presuppositional phenomena can be explained only by taking into account the cotextual sequential dimension (this was implicit, albeit in an idealized way, in Grice's criterion of cancelability), as well as the rhetorical dimension (which was implicit in Sadock (1978) and Horn's (1991) criterion of reinforceability). For a study of pragmatic presuppositions, it is necessary to move

from an analysis of predicates within single sentences to the analysis of textual structures in which the presupposition is one of the effects (*see* **Text and Text Analysis**). Presuppositions change the legal situation of speakers (Ducrot, 1972: 90*ff.*), that is, their rights and duties within a context that is being constructed along the way. The projection problem (see, among others, Levinson, 1983; van der Sanft, 1988) – namely, the problem of how the presuppositions of a simple sentence are or are not inherited from a complex sentence – may be reformulated in a pragmatic and textual perspective as a problem of the constraints, not only thematic, on coherence and acceptability that arise in the construction of a discourse (*see* **Discourse Semantics; Constraint, Pragmatic**).

2. *Anthropological-cultural-social*. Much work has still to be done on shared knowledge, on the kinds of beliefs that can be taken for granted within a given cultural and social group. Presuppositions are a way of building up such knowledge and of reinforcing it. The social relevance of this research, which might be profitably connected to work in the theory of argumentation (e.g., see Perelman and Olbrechts-Tyteca's classical analyses [1958]; *see* **Argument Structure**) is obvious. As Goffman (1983: 27) wrote: "[T]he felicity condition behind all other felicity conditions, [is]... *Felicity's Condition*: to wit, any arrangement which leads us to judge an individual's verbal acts to be not a manifestation of strangeness. Behind Felicity's Condition is our sense of what it is to be sane" (*see* **Social Aspects of Pragmatics**).
3. *Psychological*. The analysis of implicit communication, even if one takes care to avoid undue psychologizing, does require psychological adequacy. Just an example will clarify this point: we tend to choose those topics that are at least partially shared, that enable us to be allusive and elliptical; we produce 'exclusive' utterances that only the addressee can understand at once. In other words, we engage the maximum of knowledge shared between ourselves and (only) the addressee.

The pragmatic analysis of presuppositions is a task that, for the most part, still has to be performed. It is a truly vertiginous enterprise, yet one that cannot be abandoned if, moving beyond the logical relations between utterances, human communication is to be considered a relevant object of study.

Critical Introduction: Metatheoretical Presuppositions as Ideological Norms Constraining the Empirical Sciences of Pragmatics and Semantics

As a first approximation, pragmatics may be defined as the science of language use (*parole*) or the discursive functions of language, including its contextual uniqueness and variability (irregularities), whereas linguistics may be defined as the science of the abstract (decontextualizable) regularities that constitute linguistic structure (*langue*), including semantics as a formally encoded system of denotational meanings. This is a very general and common characterization of pragmatics and semantics that, however, may not be universally accepted by linguists and pragmaticians; among them, there is no consensus on what those fields are about, where the boundaries lie, or even whether we can or should draw boundaries (*see* **Pragmatics: Overview**). At the same time, most scholars nonetheless seem to think that the relationship between semantics and pragmatics is a primary metatheoretical issue, having direct and profound bearings on how things are done in these disciplines, that is, how we conceptualize the relationship constitutes primary principles, norms, or postulates at the metatheoretical level, explicitly or implicitly presupposed in the context of any scientific practices concerning language at the object level. Such metatheoretical presuppositions clearly constrain object-level activities and analyses (*see* **Metapragmatics**). Here, we may think of how meta-level phenomena such as Gricean maxims and frames are indexed by object-level phenomena such as floutings and contextualization cues, respectively, and relatively strongly constrain the interpretations of what is done in

Pragmatics and Semantics

Critical Introduction: Metatheoretical Presuppositions as Ideological Norms Constraining the Empirical Sciences of Pragmatics and Semantics

As a first approximation, pragmatics may be defined as the science of language use (*parole*) or the discursive functions of language, including its contextual uniqueness and variability (irregularities), whereas linguistics may be defined as the science of the abstract (decontextualizable) regularities that constitute linguistic structure (*langue*), including semantics as a formally encoded system of denotational meanings. This is a very general and common characterization of pragmatics and semantics that, however, may not be universally accepted by linguists and pragmaticians; among them, there is no consensus on what those fields are about, where the boundaries lie, or even whether we can or should draw boundaries (*see* **Pragmatics: Overview**). At the same time, most scholars nonetheless seem to think that the relationship between semantics and pragmatics is a primary metatheoretical issue, having direct and profound bearings on how things are done in these disciplines, that is, how we conceptualize the relationship constitutes primary principles, norms, or postulates at the metatheoretical level, explicitly or implicitly presupposed in the context of any scientific practices concerning language at the object level. Such metatheoretical presuppositions clearly constrain object-level activities and analyses (*see* **Metapragmatics**). Here, we may think of how meta-level phenomena such as Gricean maxims and frames are indexed by object-level phenomena such as floutings and contextualization cues, respectively, and relatively strongly constrain the interpretations of what is done in

the speech event in which such phenomena occur (cf. Lucy, 1993; Mey, 2001: 173–205; *see* **Maxims and Flouting**; **Constraint, Pragmatic**; **Grice, Herbert Paul (1913–1988)**). Note that such metatheoretical principles are, in social-scientific terms, evaluative norms to which the individual scientists differentially orient and against which they evaluate their behaviors; in so doing, they discursively mark their distinct group identities and constitute themselves as members of particular 'schools' (cf. Woolard and Schieffelin, 1994; Koyama, 1999, 2003; Kroskrity, 2000). Thus, these value-laden, normative conceptualizations of the relationship between semantics and pragmatics may be seen as the metalinguistic ideologizations that index the social positions and stances of particular scholars. Below, we describe the general frameworks of such ideologizations, place them in a historical context from the perspective of critical pragmatics, and examine what language users, including semanticians and pragmaticians, do with words, that is, how they (re)create their theories, disciplines, and themselves in their sociohistorical contexts (cf. Koyama, 2000b, 2001a; Mey, 2001).

Because metatheoretical conceptualizations may focus on methodological stances or the more empirical issue of how to set the boundaries of pragmatics (*vis-à-vis* semantics or 'extralinguistics,' i.e., semanticism, complementarism, and pragmaticism), we shall, for analytic purposes, deal with them separately. Starting with the former, we show the correspondences between metatheoretical conceptualizations and the sociohistorical contexts that endow them with socially interested values.

Three Methodological Stances to Pragmatics and Semantics

The Componential View

The first way to articulate the relationship concerns methodologies of, or metatheoretical stances toward, linguistic sciences. Clearly, they can be objective (deagentivized) or subjective (agentive), analytic (compositional) or synthetic (holistic), or various combinations thereof; but we may detect three ideal types in the recent history. The first of such types, best represented by the Chomskyan approach and generally characterized by objective **and** analytic attitudes, is called 'componential,' 'compartmental,' or 'modular.' It sees the linguistic sciences as analytic pursuits dealing with decomposable objects (i.e., modules) such as phonetics, phonology, morphophonology, morphology, syntax, semantics, and pragmatics, naturalistically studied by compositional methods and described independently of the particular sociohistorical contexts in which analysts are involved as social agents. Clearly, this metatheoretical stance, which underlies the organizational institutions and academic curricula of linguistics, is typical of the modern sciences coming out of Baconian natural philosophy in 17th-century England (cf. Bauman and Briggs, 2003). That is, it is the stance of the modern natural sciences (*Naturwissenschaften*), with their laws and other regularities, which try to explain empirically occurring phenomena by appealing to hypothetically idealized quasiempirical regularities ('covering laws') analytically abstracted from the total contexts of scientific activities, which are thereby decomposed into distinct fields, in our case semantics and pragmatics.

This epistemological characterization may be supplemented with a pragmatic understanding of the social and historical processes of epistemic authorization (cf. Kroskrity, 2000: 85–138). That is, the componential stance toward language is pragmatically positioned in, and presupposingly indexes, the historical context of the post-Baconian specialized sciences and, more broadly, Durkheimian 'organic society' in modernity, or the age of social specialization and the division of labor. Because the truthfulness, appropriateness, and effectiveness of any actions, including scientific ones, depend on the contexts in which they take place, this implies that the componential stance and its 'scientific' results receive their authority primarily from the post-Baconian modernization project. This project is characterized not only by social and epistemic specialization, but also by the standardizing regularization, methodical rationalization, and experimental controlling of contextual contingencies, chance happenings, and unique events, which earlier were understood as fate, epiphanies, and other phenomena originating in the heavenly universe, and transcending the sublunar, empirically manipulable space of human agency (cf. Hacking, 1990; Owen, 1994; Koyama, 2001b). Here, we must note that standardizing regularization, Saint-Simonian technocratic specialization, and Benthamite instrumental rationalization generally characterize the modern discipline of logic (or, when applied to linguistics, of formal syntax and semantics), which came to dominate American philosophy around 1900 and whose rise is precisely due to these social forces (cf. Kuklick, 1977).

The Perspectival View

The second stance is less objectivizing and more synthetic because it emerged as a critical reaction to the crisis of the Baconian sciences and the modernization project in the early 20th century. This critical reaction may be characterized as the Husserlian phenomenological movement, genealogically going back

to Hegel's totalistic dialectic phenomenology and Kant's critical philosophy and encompassing some of the early structuralists, Gestalt psychologists, and other (broadly defined) neo-Kantians who emphasized the processual nature of scientific knowledge as empirically anchored in the holistic context of human beings in their worlds, with their origin located at the *hic et nunc* of agentive experiences (cf. Jakobson, 1973). One of the critical aspects differentiating this stance from the nomothetic one of the natural sciences is the understanding of scientists and their activities as a contextually integrated part of the phenomena analyzed by the scientists themselves, here theorized as contextualized beings. Hence, the phenomenological sciences are closer to a *Geisteswissenschaft* such as Weberian interpretative sociology, in that it tries to come to grips with the dialectic fact that scientists, always already involved in their social contexts, cannot ever get rid of socially contextualized perspectives (cf. Geuss, 1981; Duranti and Goodwin, 1992). Hence, the phenomenological stance toward the linguistic sciences is characterized by a perspectival and ethnomethodological (i.e., critically agentive) understanding of such sciences, in particular the understanding that language can be studied from an objectivizing or agentive perspective and that scientific findings are largely a function of the particular methodological perspectives chosen by social agents (cf. Calhoun *et al.,* 1993; Verschueren, 1999; note the perspectivalist notion of 'seeing-as,' genealogically derived from Wittgenstein's, Nietzsche's, and Kant's epistemological focus on form, epistemology, and methodology rather than on substance, ontology, or the *Ding an sich*). In this understanding, semantics studies the linguistic phenomena that emerge when scientific agents take a deagentivizing, decontextualizing perspective, whereas pragmatics is a study of linguistic phenomena seen from the perspective of 'ordinary language users' who nonetheless critically examine **their own** linguistic activities 'from within.' Hence, pragmatics in the phenomenological tradition is a critical science **of**, **by**, and **for** ordinary language users (cf. Mey, 2001).

Here, we may note that the perspectival view is generally preferred by pragmaticians, presumably because 'perspective' is a pragmatic notion *par excellence*, whereas the componential view is preferred by semanticians. This suggests that analytic decomposition is a methodological action that displaces or suppresses perspectival indexicality, compartmentalizes linguistic sciences, and privileges (or generates) structural objects such as semantics, in opposition to pragmatics, which it relegates to the 'waste-basket' of linguistics (cf. Mey, 2001: 19–21).

The Critical Sociological View

The previously discussed methodological understanding of the sciences goes back to Kant's transcendental critical philosophy; it was the turn-of-the-century neo-Kantians, in particular, Weber, Adorno (the Frankfurt School), and other critical sociologists, who, following Nietzsche, came to squarely understand this methodological, Kantian condition of modern sciences and its consequences, especially its epistemological relativism (cf. Geuss, 1981; Owen, 1994; Mey, 2001: 315–319). More importantly, such scientists followed the critical spirit of Kantian philosophy and launched a **meta**critique of methodologically critical Kantian science and its relativism, shown to reflect and partially constitute the contextual, social condition of the age in which such science had been created, viz., modernity. In this metacritical view, what is needed is a metacritical science that can relate the critical methodological instances of Kantianism to their sociohistorical context – that is, the political-economic and other kinds of pragmatic 'reality' that have endowed these instances with plausibility, if not verity – so as to show the critical limits of methodological relativism that are inherent in its historical and societal context.

Thus, just as methodologically critical perspectivalism and its sociological metacritiques (i.e., critical pragmaticism) came out of Kantian critical philosophy, so, too, pragmatics itself and, at least in part, semantics evolved out of this philosophy. This is illustrated by the following brief excursion into the historical context in which these two fields originated.

First, we note that the term 'pragmatics' was coined by the American pragmatist Charles Morris (1901–1979), who articulated the tripartite distinction among syntax (form), semantics (meaning), and pragmatics (context), appealing to the semiotic Pragmati(ci)sm of Charles Peirce (1839–1914), which tried to base knowledge on *praxis* (actions). Peirce's Pragmati(ci)sm, characterized by the phenomenological and critical orientations of neo-Kantianism, explicitly pointed to Kant as the founder of critical sciences, primarily because Kant articulated philosophy as a **critique**, in particular of philosophy itself. Hence, post- or neo-Kantians advanced 'semantics' and 'pragmatics' as means to critically examine and articulate the foundations of modern epistemological and praxeological pursuits, respectively. More importantly, the contextual motivations for these critical sciences came from the historical conditions of the Enlightenment (or early modernity), which replaced the older schema in which *ratio* was subordinated to *intellectus* (emanating from the heavens to the sublunar human world, which was passively affected by

it) with a new schema in which reason (epistemology) came to preside over imagination, fancy, or even madness (aesthetics). This was part of the comprehensive historical shift that replaced the theocentric, religious universe of the late Middle Ages – in which the universal, catholic, and absolute truth resided in the heavens, transcending the empirical, earthly, contingent, relative, human universe – with the anthropocentric, secular universe of modernity, in which human beings became empirical and transcendental (i.e., autonomous) subjects, no longer relying on the once transcendental heavens for their existence. By the same token, philosophy became anthropocentric and relativistic too, as the sciences of, by, and for humans (cf. Foucault, 1973; Koyama, 2001b, 2003; *see* **Foucault, Michel (1926–1984)**). This transformation followed the development of commerce in Europe from the 12th–13th centuries onward, which brought together radically diverse cultures and histories, thus eventually giving rise to (1) the relativistically skeptic philosophy of Descartes, which started with doubting; (2) the speech genre of travel journals (developing into modern novels and (Alexander) Humboldtian 'natural histories,' out of which emerged modern anthropology and comparative sociology); and (3) humanism (eventually turning into philology and linguistics). The relativistic social **and** epistemic condition of modernity is correlated with the historical transfer of transcendence from the heavenly realm to the empirical realm of humans, who thus became transcendental-empirical doublets, obliged to justify themselves by means of, precisely, such metalinguistic critiques as semantics, pragmatics, and, more generally, Kantian transcendental philosophy.

Thus, modern semantics and pragmatics came out of Kantian critical philosophy and show historical characteristics of modernity, whereas philosophy (science) tries to critically examine and justify – within limits – itself because there is no longer any God (or *deus ex machina*) available to ground the human-made edifice (cf. Vico's *scienza nuova*). Post-Kantian modern semantics carries out a metalinguistic (metasemantic) critique of scientific and nonscientific languages, concepts, and (correct and literal) referential acts (cf. logical positivism, General Semantics, and the work of Ogden and Richards), whereas pragmatics (often incorporated into the social sciences, in the tradition of Durkheim, Weber, Boas, Marx, Hegel, the brothers Humboldt, Herder, and ultimately, Kant) carries out a metalinguistic (metapragmatic) critique of scientific and nonscientific discourses and other actions in the sociohistorical context of modernity and beyond. This is what the post-Kantian demand of critical science requires us to do, by reflexively examining post-Kantian sciences **themselves**, including semantics and pragmatics, and articulating their historical, cultural, social limits as shown by (1) the decontextualized, dehistoricized notion of 'truth' advanced by the semanticians who ethnocentrically assume their cultural stereotypes as universal concepts; (2) the modern anthropocentric, 'phonocentric' understanding of discourse as having its foundational origin in the *hic et nunc* of microsocial communication; and (3) methodological relativism (cf. Koyama, 1999, 2000b, 2001b, 2003).

Thus, the third, critical-sociological, view tries to transcend modern perspectivalism and methodological relativism by showing their historical limits and advancing a transcendentally ideal **total** science that attempts to integrate a legion of specialized sciences and perspectives, in particular trying to overcome the division between the theoretical (conceptual, analytic, and linguistic-structural) and the pragmatic (empirical, social, and contextual) (cf. Koyama, 2000a). This approach, which underlies Pragmati(ci)sm as a project seeking to anchor theoretical knowledge in contextualized actions, and pragmatics as a project aimed at the unification of theoretical and applied linguistics, can be called 'semiotic,' insofar as semiotics is a science that tries to integrate decontextualized and contextualized epistemic, praxeological, **and** aesthetic phenomena, separately studied by specialized sciences, under the unitary umbrella of semiotic processes anchored in the pragmatics of social actions and events. In this view, it is the socially embedded discursive interaction that contextually presupposes or even creates the variety of perspectival stances assumed by social agents such as linguistic scientists and language users. Thus, this view is less agentivist than the phenomenological one in that it tries to articulate the contextual mechanisms that give rise to agentive, perspectivalized, and ideologized accounts and uses of language. Such a 'discursive-functional' approach was advanced by Peirce, Sapir, Whorf, Jakobson, Bateson, Hymes, and other semioticians, one of the most important frameworks being Jakobson's (1960) model of the six functions of (linguistic) communication: the referential, emotive, conative, phatic, poetic, and 'metalingual' (metalinguistic, metacommunicative) functions (*see* **Jakobson, Roman (1896–1982)**). The critical significance of this framework is that it is a model of linguistic phenomena reflexively including itself (cf. Lucy, 1993; Mey, 2001: 173–205): Any linguistic theorizing or understanding, be it explicit or implicit, whether carried out by professional linguists or ordinary language users, can be characterized in terms of the metalinguistic (metasemantic and metapragmatic) functions of discursive interaction. In this model, semantics is characterized as the

metasemantic function of discursive interaction, that is, the system of the symbolic signs that discursive interactants believe exist prior to the discursive interactions in which those signs are presupposingly used to interpret the referential 'meanings' (what is said) of such interactions; on the other hand, pragmatics is equated with discursive interaction, encompassing all six functions, including the metasemantic function (to which pragmatics in the narrow sense is opposed) and the metapragmatic function, that is, the principles, maxims, norms, and other reflexive devices for textualization (framing, intertextual *renvoi*, and Bakhtinian voicing) that language users such as linguists use in order to regiment, interpret, and create referential and social-indexical meanings (i.e., effects) in discursive interactions (*see* **Principles and Rules; Dialogism, Bakhtinian**). In the next section, we articulate the relationship between semantics and pragmatics in this critical view, specifically in relation to the boundary problem.

The Boundary Problem

As has been noted, we may articulate the relationship between pragmatics and semantics in terms of the empirical boundaries between them and between pragmatics and extralinguistics. Obviously, how we distinguish semantics from pragmatics may significantly affect how we delimit pragmatics from 'the beyond,' and conversely.

Semanticism

First, as to the boundary between semantics and pragmatics, we may discern three approaches: semanticism, pragmaticism, and complementarism. Semanticism envisions pragmatics as the extension of semantically encoded yet metapragmatically characterizable categories (especially moods and *verba dicendi*, or verbs of saying), just as traditional logic has understood pragmatics (discourse) as the extensional universe onto which intensional (i.e., metasemantically characterizable) categories are projected. Naturally, semanticism is aligned with the decontextualized, analytic methodological perspective and sees language in use from the metasemantic perspective of the denotational code (linguistic structure) presupposingly used by language users, including linguistic scientists, to interpret the referential significances of discursive interactions in which they are involved as discourse participants. Hence, this approach, typically taken by the philosophers of language such as Austin and Searle, characteristically uses the method of 'armchair' introspection, in which only the presupposable (and referential) aspects of communicative processes may readily emerge. This approach generally excludes the social-indexical aspects of pragmatics, particularly as regards group identities and power relations among discourse participants and other contextual beings, inasmuch as these are **created** (vs. presupposed) in discursive interaction and only coincidentally, indirectly, or opaquely related to linguistic-structurally encoded symbols (cf. Lucy, 1992; Mey, 2001). In this approach, pragmatics is mostly reduced to metapragmatically characterizable types in what essentially is a semantic, denotational code; examples are mood/modality/tense categories, verbs of saying, pronouns, and other shifters (i.e., 'denotational–indexical duplexes'; cf. Lee, 1997) or their psychological correlates, as observed in Austin's 'performative utterances' and Searle's 'primary illocutionary forces,' allegedly underlying the perlocutionary effects regularly created by the indirect (nonliteral) use of the tokens of such types (*see* **Deixis and Anaphora: Pragmatic Approaches; Speech Acts; Austin, John Langshaw (1911–1960)**). Hence, this approach can be characterized as denotationalist, universalist, and presuppositionalist; it is based on, and expresses, a consensualist linguistic ideology adopted by the scientific agents who, like many other language users, are inclined to see only or primarily the denotationally explicitly characterizable parts of language (cf. Lucy, 1992), while their social interest is limited to seeing language *in vitro* (vs. *in vivo*), essentially consisting of a set of universal categories commonly presupposed rather than contextually created in discursive interaction (cf. Mey, 2001). Historically, this ideology derives from the 17th-century Lockean ideas about language and communication that started to prescribe and advocate, against the rhetorical practices of Scholastic disputants and the radically egalitarian Puritans, the transparently referential ('correct and literal') use of language based on the 'universal public (i.e., bourgeois) consensus' about the proper, cooperative, rational use of language that should be presupposed by 'anyone' (in reality 'Modern Standard Average Middle-Class Man'; cf. Silverstein, 1985; Bauman and Briggs, 2003).

Complementarism

Unlike semanticism, complementarism advocates the coexistence of semantics and pragmatics as 'different but equal' disciplines. Hence, it is compatible with both the compartmental and perspectival methodologies, as well as with the general ideologies of modern liberalism, relativism, and specialization. This may partially account for the current popularity of this approach, at least since the demise of the more ambitious projects of Generative Semantics and Searle's semanticism in the 1970s (cf. Koyama, 2000b) (*see* **Generative Semantics**). The approach, espoused by

mainstream pragmaticians such as Leech (1983) and Levinson (1983), has its roots in Grice, who set up the uniquely pragmatic Cooperative Principle to delimit and save the symbolic realm of logico-semantics from the caprice of contextual variability and irreducible contingency (*see* **Cooperative Principle**). As this indicates, insofar as complementarism tries to construct a kind of pragmatic theory that complements the semantic theory of decontextualized signs, it is inclined to focus on pragmalinguistics, that is, the aspects of pragmatics adjacent to and compatible with semantics, such as the universal principles, maxims, and other regularities of language use that can be fairly transparently linked to propositions and other referential categories. Thus, complementarism may be characterized as a weak version of semanticism that does not try to reduce pragmatics to semantics but attempts to create a pragmatic correlate of semantic theory, as witnessed by the affinity between Searle's semanticist doctrine of indirect speech acts and Grice's complementarist doctrine of implicature or, more fundamentally, by the referentialist, universalist, rationalist, and consensualist characteristics shared by traditional semantics and the pragmatic theories advanced by Grice and Levinson.

From Complementarism to Pragmaticism

Nonetheless, complementarism is distinct from semanticism insofar as the former advances a uniquely pragmatic principle (or perspective). This principle (or perspective) is communication, a notion that conceptualizes discursive interaction as opposed to linguistically encoded semantic categories (even though communication is still often taken as the intentional correlate of semantic categorization). This shift from decontextualized code to contextual process is also observed in the robustly pragmatic understanding of presupposition that has emerged in the wake of Karttunen's complementarist distinction between 'semantic' and 'pragmatic presuppositions' (cf. Mey, 2001: 27–29); in the discursive-functional model of communication, presupposition is a fundamentally pragmatic contextual process rather than an essential property of semantic types or their tokens. Discursive interactions indexically presuppose and create their (con)texts, yielding contextual appropriateness and effectiveness, both in the referential and social-indexical domains of discourse. The focus of pragmatics is thus on the discursive interactions that indexically create referential and social-indexical texts by indexically presupposing contextual variables, including but not limited to metalinguistic codes such as metapragmatic principles and metasemantic relationships (*see* **Presupposition**; **Pragmatic Presupposition**).

Thus, complementarism may lead to the kind of pragmaticism that tries to include semantics as a part of the all-encompassing pragmatic processes of presupposing and creative indexicality in both referential and social-indexical dimensions, involving not just ordinary language users but also linguistic scholars and including not just linguistic but also extralinguistic (sociohistorical) domains. There is, however, another, reductionist kind of pragmaticism, which is actually a variation of complementarism that narrowly limits the realm of pragmatics and exclusively deals with the part of pragmatics that correlates with semantics – the area of referentially focused pragmatic regularities. For instance, in Relevance Theory, the dialectically indexical processes of presupposing contextualization and creative textualization in discursive interactions are theorized exclusively from the referentialist perspective that tries to relate 'what is said' (referential text) to 'what is meant' (rather than to 'what is done'), the gap between the two being bridged by the ideological assumption that discursive participants universally share the rationalistic and consensualist notions of economy, cooperation, and regular and eufunctional communication (cf. Mey, 2001: 179–181). Hence, this approach excludes the vast realm of pragmatics dealing with social conflicts in group identities and power relations, as well as historically contextualized contingent happenings, which can always defeat regularities and other contextual presuppositions and create different presuppositions and texts (cf. Auer and Luzio, 1992; Koyama, 2001a) (*see* **Relevance Theory**).

Historical Contextualization of the Ideologies of Pragmatics and Semantics

Thus far, we have explored how the three methodological stances are related to how we define the disciplinary boundaries and noted the correspondence between the methodological scale, stretching from componentialism to perspectivalism to critical pragmaticism, and another scale, extending from semanticism to complementarism, reductionistic pragmaticism, and total pragmaticism. Like any ideology, this configuration of metalinguistic ideologies is also embedded in the sociohistorical context; thus, we may observe a historical drift of pragmatics from componentialism and semanticism to perspectivalism and complementarism and, finally, to total and critical pragmaticism (cf. Koyama, 2001b).

Again, let us start with Kant's critical turn, which yielded two traditions: the semantic and the social scientific (i.e., pragmatic). Whereas Kant's central concerns were '(re)cognition' and 'judgment,' behind which the problematics of 'meaning' and 'language'

were still hidden (cf. Coffa, 1991), Frege's (1848–1925) later discovery of predicate logic replaced the Kantian notion of synthetic judgment (or value) with analytic logic and the notions of 'proposition' and 'sentence,' further divided into 'force' (assertoric, interrogative, imperative, and so on) and propositional content (represented by structurally decomposable units such as the subject, predicate, and their subcategories). This led to the birth of modern semantics, as it came to be pursued by Russell (1872–1970), Carnap (1891–1970), Tarski (1902–1983), and Quine (1908–2000), as well as by the linguistic formalists of the Copenhagen and the Neo-Bloomfieldian Schools, whose impressive successes allowed the componential semantic tradition to penetrate into more empirical disciplines such as psychology and anthropology, where 'ethnoscience' came to flourish in the mid-20th century (*see* **Anthropology and Pragmatics**). Moreover, the semantic traditions of Carnap and the Neo-Bloomfieldian structural linguists, especially Harris (1909–1992), converged in Chomsky (1928–), whose generativism began to dominate linguistics in the 1960s, when the semantic tradition moved more deeply into the empirical fields, thereby giving rise to empirical semantics, as witnessed by the rise of Generative Semantics, fuzzy logic, and Rosch's prototype semantics in the late 1960s to mid-1970s, eventually congealing into today's cognitive linguistics (*see* **Cognitive Linguistics**).

Such was the evolution of the branch of the post-Fregean semantic tradition that focused on propositional content. In contrast, the other branch, focusing on 'force,' was developed by the Ordinary Language Philosophers, starting with Austin, who translated Frege's *œuvre* into English, to be followed by Searle, Grice, and others (*see* **Grice, Herbert Paul (1913–1988)**). This branch is usually called 'pragmatics,' but (as we have already seen) it is actually a kind of empirical semanticism, dealing with pragmatic matters only insofar as they can be systematically related to propositions or referential texts ('what is said'; *see* **Pragmatics, Overview**).

In the early days, modern pragmatics was dominated by Speech Act Theory and by Gricean thinking: It was practiced by extending the methodological orientations of logic and structural linguistics, with their focus on denotational regularities. In those quasipragmatic theories, contingent occurrences of actual language use were still theorized as tokens of some regular Searlean type of speech act (or speech act verb) or some Gricean postulates (principle and maxims) rather than as indexical events presupposingly contextualizing other indexical events, indexical event types (e.g., speech genres, sociolects, and dialects), and symbolic structures and contextually creating certain pragmatic effects (cf. Auer and Luzio, 1992; Koyama, 2001a) (*see* **Pragmatic Indexing**). In short, the notions of context and contextualization, which constitute the core of our pragmatic understanding, were yet to be given full theoretical significance, especially in comparison with the anthropological tradition, which, since the days of Malinowski and Sapir, has focused on the (socially situated) 'speech event' (cf. Gumperz and Hymes, 1964; Duranti and Goodwin, 1992; Duranti, 2001; *see* **Context, Communicative**). Thus, it was only in the late 1970s and 1980s, when anthropology and linguistic pragmatics began to influence one another more intimately, that the genuinely pragmatic view of 'pragmatics' as the idiographic, ethnographic, historiographic science of contextualization started to emerge. Then, it became clear that the (con)text indexed by language in use ('what is done') includes not just 'what is meant' (i.e., the part of the context that may be regularly related to 'what is said'); rather, the context of language in use is primarily captured by social-indexical pragmatics dealing with 'what is done,' that is, with the power relations and group identities of discourse participants, involving their regionality, class, status, gender, generation, ethnicity, kinship, and other macrosociological variables, indexed and actualized in microsocial speech events to entail some concrete, pragmatic, 'perlocutionary' effects (*see* **Power and Pragmatics**). The changing focus is reflected, first, in the move from the early quasipragmatic theories, which generally embraced the componential view and focused on illocutionary and other propositionally centered referential pragmatic regularities in microsocial speech events, to the next generation of more full-fledged pragmatic theories, which based themselves on the perspectival view, paying attention to the social-indexical (especially cultural) aspects of pragmatics as well. Further, the changing focus is also observed in the more recent move toward a 'total pragmatics,' with its critical view and its emphasis on the (micro- **and** macro-)contextual aspects of pragmatics. These aspects focus especially on a social-indexical pragmatics (including not just culture but also class, gender, and other sociological and historical variables) that views as its core 'what is done' (the pragmatic, *praxis*), a special subset of which is constituted by 'what is said' (referential practice) and by linguistic structure, including semantics (as presupposingly indexed in referential practice) (cf. Koyama, 2000a, 2000b, 2001a; Mey, 2001). Only then can semantics and pragmatics be united in their proper contextualization within the macrosocial historical matrix.

Pragmatics of Reading

J L Mey, University of Southern Denmark, Odense, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Reading is a matter of communication. Not just in the usual sense that an author has a message to communicate to a reader (a story, the description of an experiment, an opinion about an event, and so on), but the reader also communicates with the author by showing interest in the story, by ratifying the experiment described, by approving of the opinion proffered, and so on. This 'active communication' is often expressed in writing or orally (e.g., by talking about the story to others, by commenting on the experiment, or by writing a commentary to the editor of the paper or journal in which the author's opinion had appeared). Usually, though, readers 'vote with their eyes', silently, by simply sharing their

precious time with authors and entering into a readerly relationship with them – a relationship that starts when prospective readers acquire the authors' written product (a book, scientific journal, etc.).

Prospective readers become real readers by *negotiation*. More will be said on this later; for the moment I simply emphasize the fact that negotiation involves people (here, author and reader), and essentially happens on the basis of some common *language*. Readers must be able to understand the language used by authors – not just in the sense of a common 'national' language, but also with regard to the different levels of expression and local and professional idioms. Readers' reactions are also expressed in language (internally, by 'following' authors' narrative paths, or externally, in the form of oral or written comments). Moreover, in all of this, we must not forget the environment in which both readers and authors are situated: their social *context* is what makes mutual understanding and communication possible (*see* **Context, Communicative**).

Reading, as a communicative process, relies on the presence of users in a social context – a context mediated by language. In other words, reading can be characterized as a *pragmatic* process, involving "the study of the use of language in human communication as determined by the conditions of society" (Mey, 2001: 6) (*see* **Pragmatics: Overview**).

Negotiation and Reading

In all reading, there is negotiation. Authors have to persuade readers to take the story seriously, to enter the 'fictional space' (Mey, 1994). To do this, the author ensures that whatever is said in the story will be taken at 'story value' by the readers, and that no hitches will develop in the smooth spinning of the narrative yarn. When this condition is not fulfilled, the texture of the story is disrupted: a hole appears in the narrative fabric or a 'clash of voices' occurs (Mey, 2000) (*see* **Literary Pragmatics**).

Authorial persuasion displays parallels with another kind of negotiation, the business deal: one puts certain things on the table (an offer, a counteroffer, conditions, etc.), while other matters are held back, kept 'under the table' (sometimes even after the deal is concluded). To buttress one's argumentation in the negotiation process, one must produce evidence of credibility: previous contracts, a reputation, 'goodwill', concrete enticements (such as money, again often under the table), and above all, a proof of trustworthiness based on one's credentials as a serious negotiator. These proofs can more or less subtle; less subtle are outward appearance such as the right kind of business attire; personal accouterments showing status (watch, jewelry, tie, correct hair styling including – if applicable – facial hair, etc.; even such minor things as flying the right airline in the right class can be important); the right language to bring to the negotiation table; correct manners; and most of all, a thorough knowledge of the matters to be discussed. In all this, as Dr Chester Karass incessantly admonishes us: "In business you do not get what you deserve, but what you negotiate."

There are similarities between business negotiation and creating contracts between author and reader. The author has to speak the 'right' language (in the sense of: appropriate to the occasion). That is, the narratorial voice and the voices of the characters should be balanced, both with each other and between themselves (for details, see Mey, 2000). But also, the author should be knowledgeable about what is on the narrative negotiation table: the voice of the text should be credible, as regards the factual circumstances of the narrative. Details about times and places should accord with the facts as they are familiar to both author and readers; alternatively, the details should be such that the readership can live with them for the duration of the narrative. The latter requires author and reader to negotiate, as we will see in the following.

Negotiating the Scene

The details of time and place mentioned above belong to a metaphorical 'scene.' In it, characters play their roles, and utter their lines; their scenic location in time and place makes their roles trustworthy and their voices credible. Similarly, the characters of a story have their particular roles and voices, recognized as authentic and consistent by the readership. The scene thus is both the condition for, and the result of, a successful reader-author relationship (*see* **Literary Pragmatics**).

If an author invites us into an unfamiliar scene, possibly remote from our own (as in many historical novels or in modern science fiction), negotiation is necessary to make the unfamiliar authentic: the strange world into which the author introduces us should not be unacceptably strange. We are all 'strangers in a strange land,' but we are supposed to stay inside this "ambiguous territory" (as Julio Cortázar (1985) puts it), at least during the narration, and not run away, scared by unfamiliar surroundings and technological innovations.

Often, such innovations and strange environments are projections from familiar situations and technologies which now appear distorted or exaggerated. People travel with the speed of light in *A hitchhiker's guide to the galaxy*; men have

menstrual periods in Ursula Le Guin's *The left hand of darkness*; banal objects such as eyeglasses become sophisticated prosthetic body parts able to tell the time, access databases, and orchestrate weaponry, as happens in William Gibson's *Neuromancer*; and so on. If successful, such 'defamiliarizing' features strengthen the ties between author and reader; the 'bestrangement' that occurs is a powerful factor in the negotiation discussed above.

'Bestrangement' and Reader's Role

Above, we saw how the success of a literary text depends upon readers accepting and voluntarily entering the 'scene' created by the author. One way to overcome the readership's reservations is to make the fictional world attractive by appealing to readers' sense of familiarity and normativity ("those people are just like us"). Another, far more powerful, way to intrigue readers is to make things difficult or to titillate readers with special narrative effects. Especially important is 'bestrangement', which exploits unfamiliarity and disregard for narrative conventions. It is based on a 'willful suspension of disbelief' (in Samuel Taylor Coleridge's classic formulation; 1817, 1956), an acceptable and accepted infraction of the rules as normal authorial behavior. At the same time, this infraction is what makes a 'bestranged' piece of literature interesting.

As Shklovskij put it, to see things as they are, we need to escape the 'tyranny of the ordinary,' the established ways of viewing the world as codified through language, especially its literary and poetic varieties. The phenomena of the outside world reveal their true identity only if seen with a stranger's eyes. Conversely, we may be able to grasp things as they are in themselves by transforming into strangers and outsiders. The point is to *see* the world, not just to recognize it: art re-creates our experience of the world and its objects, causing us not just to register and recognize them but to see them. Shklovskij (1917: 14; my translation) declares that "Art does this by 'bestrangement': by making things unfamiliar, by making their shapes hard to recognize and 'strange'."

The importance of changing perspective has long been recognized by visual artists. The contemporary Danish painter Per Kirkeby, writing about his 19th century colleague N. A. Abildgaard, says: "At intervals the earth has to be made flat in order that we may see clearly" (Kirkeby, 1993: 14). But the perspective has to be grounded in an acceptable context; the scene must be 'natural' (even though not necessarily naturalistic, in the common sense of the word). This includes the characters and their roles, as expressed in dialogue, both the one that is verbally expressed and the underlying, invisible subtitles that are left to the readers' imagination and co-creative activity (*see* **Dialogism, Bakhtinian**).

Negotiating the Fictional Space

Perspective and Change

How does a competent or 'versatile' (Tsur, 1992) reader deal with changes of perspective in literary texts? Three questions may be asked:

(1) What happens when an author disturbs the temporal and spatial fabric of the story?

(2) What are the author's aims in making the reader lose touch with normal, perceived reality?

(3) In what ways and to what extent does the author realize those aims?

The first question is about the technique of 'bestrangement' in fiction, as discussed above.

The second question touches on the author's need to establish the scene or fictional space as an independent world where normal relations of time and space may be suspended. The reader must see the normal reality as abnormal and the deviant reality of the fictional space as normal.

The third, more general, question deals with how a fictional space is built up by the characters playing out their roles on the fictional scene, and by the intricate interplay of the voices that express the characters' stance toward, and participation in, the fictional reality. As for the readers, they enter the fictional scene *qua* readers, and participate in the world-building by expressing themselves in a 'readerly voice,' manifesting their active cooperation in the textual process.

Disturbing Reality

The initial negotiation in the 'act of reading' (Iser, 1982) is implicit in the act of buying or borrowing a book; continuing negotiation depends on our perseverance as 'competent readers' (see Tsur, 1992; Mey, 2000).

During our reading, the implicit contract will have to be renewed: either by our continued reading, or by an explicit move. Here, we may distance ourselves from the text (physically, by discarding the book, or mentally, by losing interest or stopping reading); alternatively, we may get so involved in the story that we start inhabiting the fictional space as if it were a real one. Our 'bestrangement' may express itself in a feeling of dislocation, as when we wake up in unfamiliar surroundings and don't know where we are or how we got there. The world may have been changed

so that we see its true reality, as when we contemplate a surrealist painting.

A prime example of this process is found in a famous scene from *Anna Karenina*. Returning by train from Moscow to St. Petersburg, after the ball at the Oblonskij palace and her spectacular dance with Vronskij, Anna is reading a trashy English story about a young nobleman and his aspirations to a manor and a baronetcy. Realizing that she is getting involved in the silly story, Anna experiences a sense of shame, and closes the book.

> The hero of the novel had already started on the path toward achieving his English happiness, a baronetcy and a manor, and Anna wanted to join him in his journey toward that manor, when she suddenly realized that he ought to be ashamed, and that she ought to be ashamed likewise. But what [should] he [be] ashamed of? "And what [am] I [to be] ashamed of?" she asked herself in irritated wonder. (*Anna Karenina*, I: xxix, p. 114 in the 1962 edition; translation mine.)

Like many readers, Anna enters the 'fictional space' and participates in the novelistic life on stage. When readers 'identify' with a particular hero or heroine in a story, they do so actively, with their "whole body and deeds," as Bakhtin says. They can also give notice, and 'cancel' the reading contract, by either putting away the book, or assuming a critical stance toward it.

Anna, however, cannot escape the powerful hold of the fictional space she has entered. In the end, her identification with the hero's world, including the feeling of shame, turns out to be grounded in the real world: her burgeoning love for Vronskij, whom she then goes out to meet on the platform when the train makes the next stop.

A further, particularly gripping illustration of Anna's entering the fictional scene and participating in it, more or less against her will, comes later in the chapter. Here, Anna finds her thoughts wandering from the text she is reading, to her own, actual situation. This slipping is not simply a matter of Anna being preoccupied, having her thoughts elsewhere; rather, it is her entry into the fictional space of the novel that forces Anna into a dialogue with her own self, with her 'inner' voice, on a theme only partly suggested to us (and to her) by the text. Anna reviews her pleasant memories of the dance and of Vronskij's tender loving face. Suddenly, a new feeling surges up.

> But at the same time, at exactly the same spot in her remembering, a feeling of shame made itself strongly felt; as if an inner voice, precisely whenever her thoughts went back to Vronskij, told her: "Hot, very hot, burning." "So what of it?" – she said to herself peremptorily, sitting up in her chair. – "What on earth does this mean? Am I perhaps afraid to look this thing straight in the face? Then what of it? How should there be, how could there be, between me and this stripling officer, any other relations than I would have with any normal acquaintance?" She let out a contemptuous laugh and went back to her book, but this time she was totally unable to concentrate on her reading. She took the paper cutter and drew a line on the window pane, then put its smooth, cool surface to her cheek and could barely refrain from bursting out in cries of joy – a joy that, coming from nowhere, suddenly engulfed her. (*Anna Karenina*, I: xxix, 1962 ed., p. 114; my translation.)

Anna is overcome by a near-hallucinatory state of euphoria. At the end of the chapter, the series of intense emotional experiences culminates in her finding herself on the station platform of 'Bologov' (actually, Bologne), where her famous, and fatal, encounter with Vronskij is about to happen.

Anna's reading of her trashy novel is 'set up' (Mey, 2001: 211–212) by her circumstances after the initial meeting with her future lover. Dialoguing with the text, Anna is engaged in what I call a *pragmatic act* of reading (Mey, 2001: 252ff) (*see* **Pragmatic Acts**). This is most clearly seen in the passage above where Anna, as reader, actually is engaged in a kind of parlor game with an 'inner voice,' telling Anna that she is getting "[h]ot, very hot, burning," ever closer to discovering the true nature of her confused state of mind and lack of concentration: she is in love.

This discovery, of course, does not result from the act of reading as such. Still, the text, in its dialogic foreplay with Anna as reader, does lead up to the real thing: her textual immersion results in a sexual de- or even re-construction. Anna's hidden emotions and the recognition of her true feelings are lying in waiting just outside her novel's fictional space. As soon as she puts the book away and leaves its fictional space, having symbolically cut her textual ties by drawing a line on the compartment window with her paper-knife (a metaphoric 'text cutter'), she crosses a physical threshold by leaving the compartment and exchanging her fictional space for the real world: text for sex. It is in this real space, physically materialized as the storm-blown, snow-covered railway platform at 'Bologov', that the textually de-constructed, sexually re-constructed Anna meets Vronskij in what Bakhtin has called an "open-ended dialogue of life," with the well-known consequences that form the backbone of the dramatic plot for which Tolstoy's novel is justly famous (*see* **Bakhtin, Mikhail Mikhailovich (1895–1975)**).

Does the Reader Have a Voice?

In all this, the role of the reader, as an active participant in the building of the story world, through 'creative reading' has yet to be determined, but the reader's role presupposes a 'readerly voice' in the orchestration of the text. When discussing literary activities around text, we focus on authors but often gloss over the important role of the reader. Readers approach the text with a particular set of preconditions which, from a reader's point of view, make the text possible; there is no reader's text without a reader, because stories describe *possible* worlds, not actual occurrences: only readers can bring these possibilities into existence.

Speaking on the general conditions of novelistic work, the Czech author Milan Kundera has remarked:

> A novel examines not reality, but existence. And existence is not what has occurred, existence is the realm of human possibilities, everything that man can become, everything he's capable of. Novelists draw up the *map of existence* by discovering this or that human possibility. But again, to exist means: "being in the world." (Milan Kundera, *The art of the novel*, p. 42.)

Only through the intermediary of an actually existing reader can the text achieve *existence*. A text, taken by itself, is merely an author's product, and as such only realizes a *possibility* – one out of the many ways of 'being in the world' that a text assumes by being consumed by a reader (*see* **Literary Pragmatics**).

Certain schools of literary criticism have emphasized a so-called 'objective' approach to text understanding and analysis. In this view, the text, the whole text, and nothing but the text should be the target of our investigation (see Mey, 1994 for a critique). To see the limitations of this kind of approach (usually referred to as 'New Criticism'), consider the following passage from a contemporary novel by Jay McInerney, *Brightness falls*:

> [The talk here is about money; the context is that of the attempted hostile takeover of a New York publishing house by another firm. The manager of the threatened enterprise is speaking.]
>
> Nobody *pays* for anything anymore, that's the fucking problem. They're totally leveraged. Bridge loans, junk bonds, whatever. The money's out there. Money's cheap. The banks used to be like convent girls, you couldn't get a feel without a marriage license. Then Drexel started to practically give it away, and now they've all got red lights on over the door. (McInerney, 1992: 217; emphasis original.)

The excerpt describes the United States in the late 1980s, when the world of finance was characterized by an expanding money market with no real assets to back it up (cf. "junk bonds"). Buying something big without having the money was possible if you had "leverage," that is to say, you were able to find some of the ("cheap") money you needed, waving your hands at the rest. You could borrow the money, preferably on borrowed, or even fake, collateral. All this was because the banks had a cash glut: interest to wealthy overseas depositors had to be paid on time, so the money was "practically given away," even to less than serious borrowers.

The text is distinguished by an intricate use of composite metaphors, appealing to the (mostly) male sexual experience: 'convent girls,' 'feel,' 'marriage license,' 'red lights.' But many respectable firms became players in this risky game (such as "Drexel," the since failed Wall Street broker firm of Drexel Burnham Lambert).

The point to note here is that reading such a text requires active, understanding, co-creative readers who are at least aware of the way American males of a certain type regard their female counterparts, and where sexual activities are mainly configured in terms of finance: buying and selling, negotiating a deal, and so on. The reader's participation in the textual process is necessary for it to be understood properly, or understood at all. This is why texts from earlier periods or far-away cultures often strike us as insipid or totally opaque. Conversely, even nonfictional texts exhibit some of the same characteristics as fictional prose.

For example, Stanley Kauffman concludes a scathing movie review with the innocuous remark: "The suggestion in the title [of the film] is off target" (Kauffmann, 1973: 41). Because the reader has been informed earlier in the review that the title is *Up the sandbox* (National General, 1972), the reader is obliged to supplying the missing reference and provide the proper 'target.' This is made possible by the author's implicit appeal to the reader to identify certain common vulgar English expressions containing a propositional phrase *Prp* + *NP*, where the *Prp* in this particular case is *up*, while the *NP* is ({*the, yours,* . . . } + *N*), where *N* stands for (*Body Part* [+*Intimate*]). The competent reader will rise to the challenge posed by the author's unfinished expression, thus actively taking part in the creation of the fully fledged piece of text.

Conclusion

As Scholes (1982) remarks, we cannot add to the facts of a story (just as we normally cannot 'do' anything

with the objects in a painting or the parts of a sculpture). However, we can place the facts in their proper environment: we can extend the story into other stories, especially our own, and into the stories that we are familiar with from our reading. As Scholes says, "As semiotic interpreters we are not free to *make* meaning, but we are free to *find* it by following the various semantic, syntactic, and pragmatic paths that lead away from the words of the text" (1982: 30; italics in original).

The reader who is thus able to ''find meaning' in the text (the *Lector in fabula*, Eco, 1979)is also a *co-creator* of the text. To collaborate with the author, readers follow the "various syntactic, semantic, and pragmatic" paths that lead into as well as "away from . . . the text." Readers who can do this are competent or 'versatile.' In particular, competent readers work with the author to construct the 'fictional space' in which the characters play their roles to create, not a dead letter, but a living text re-created in the reader.

This reader-author relationship is a relation of mutual influence. If reading can be called a game, it is one in which each side's moves are affected by and affect those made by the other; it is a play in which all the players have a voice, including the reader.

Pragmatics: History

B Nerlich, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Pragmatics, the study of sign use and sign users in situations, is usually considered to be a fairly recent addition to the language sciences (*see* **Pragmatics: Overview**). The term *pragmatics* is generally said to date back to the work of the American semiotician and behaviorist Charles Morris and his distinction of the three parts of semiotics: *syntactics*, *semantics*, and *pragmatics* (*see* **Semiotics: History**). The foundations for pragmatics as a linguistic discipline are regarded as having been laid by ordinary language philosophers and speech-act theorists such as Ludwig Wittgenstein, John L. Austin, John R. Searle, and H. Paul Grice (*see* **Austin, John Langshaw (1911–1960)**, and **Grice, Herbert Paul (1913–1988)**).

By adopting this new approach to language, studied as a kind of human action, philosophers and

Abstract:

A pragmatic approach to reading implies an open-ended invitation to the reader to join the author in the co-creation of the story, by filling in the 'holes' that are left in the text. Just as the 'said', a speaker's explicit verbal act, in many cases is dispensable, given the listener's pragmatic understanding the 'unsaid', so too the reader's act of understanding depends not only on what is found in the actual text, but on the total context, the 'fictional scene', in which the words make sense as spoken by the 'actors'. Reading thus presupposes an active collaboration between author and reader; it is this spontaneous, but mostly unconscious 'plugging' of the textual gaps that characterizes us as competent and 'versatile' readers.

Biography:

Jacob L Mey (b.1926) is Professor Emeritus of Linguistics at the University of Southern Denmark. Previous appointments include the University of Oslo, Norway; the University of Texas at Austin, Texas; Georgetown University, Washington, D.C.; Yale University, New Haven, Conn.; Tsukuba University, Japan; Northwestern University, Evanston, Ill.; City University of Hong Kong; Goethe University, Frankfurt am Main; Universidade Estadual de Campinas, Sao Paolo, Brazil; Universidade de Brasília, Brasília; DF, the University of Haifa and Haifa Technion, Israel, as well as numerous other institutions of research and higher learning. Jacob Mey's research interests concern all areas of pragmatics, with an emphasis on the social aspects of language use, the pragmatic impact of computer technologies, and the pragmatic use of literary devices. Among his publications in these areas are *Pragmalinguistics: theory and practice* (The Hague: Mouton, 1979); *Whose language? A study in linguistic pragmatics* (Amsterdam/ Philadelphia: Benjamins, 1985), Pragmatics: An Introduction (2001). This book has been translated into Japanese, Korean, and Chinese. A recent publication is *As Vozes da Sociedade* (*The Voices of Society*; in Portuguese) Campinas, Sao Paolo: Mercado de Letras, 2002). For the new field of Cognitive Technology (CT), he has written and edited numerous articles and books and co-organized several international conferences (together with Barbara Gorayska). The main interest of CT is to study the effects of the computer on the human mind, and vice versa, how the mind determines the uses we make of the computer as a tool. Among Jacob Mey's other main interests are the theory of literature and poetics (2000). Jacob Mey is founder (with Hartmut Haberland) and chief editor of the monthly *Journal of Pragmatics* (Oxford: Elsevier Science). He also edits *RASK: International Journal of Languages and Linguistics* for Odense University Press. Among his other edited volumes are two readers on Cognitive Technology (1996, 1999), and the 1100-page *Concise Encyclopedia of Pragmatics* (1998), all published by Elsevier Science. Jacob Mey holds an honorary D.Phil. degree from the University of Zaragoza, Spain. He is a member of various professional organizations, such as the Linguistic Society of America, the Copenhagen Linguistic Circle, and the International Pragmatics Association (of which he is a member of the Consultative Board). He is Editor or Member of the Advisory Board of a number of series and journals, such as *Pragmatics and Beyond* (Amsterdam), *Anthropological Linguistics* (Berlin), *Discourse and Society*; *Text; Language and Literature* (Liverpool); *Miscelánea* (Zaragoza); *Psyke og Logos* (Copenhagen); *Sémantique et Pragmatique* (Orléans), *Cadernos de Linguagem e Sociedade* (Brasília), and others. In 1998, he was elected to the office of Vice-President of the newly founded Society for Cognitive Technology.

Pragmatics: History

B Nerlich, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Pragmatics, the study of sign use and sign users in situations, is usually considered to be a fairly recent addition to the language sciences (*see* **Pragmatics: Overview**). The term *pragmatics* is generally said to date back to the work of the American semiotician and behaviorist Charles Morris and his distinction of the three parts of semiotics: *syntactics*, *semantics*, and *pragmatics* (*see* **Semiotics: History**). The foundations for pragmatics as a linguistic discipline are regarded as having been laid by ordinary language philosophers and speech-act theorists such as Ludwig Wittgenstein, John L. Austin, John R. Searle, and H. Paul Grice (*see* **Austin, John Langshaw (1911–1960)**, and **Grice, Herbert Paul (1913–1988)**).

By adopting this new approach to language, studied as a kind of human action, philosophers and

linguists hoped to overcome an overly narrow study of language as a closed system to be analyzed in itself and for itself, as advocated in structuralist traditions of linguistics after Ferdinand de Saussure and Noam Chomsky. Since the 1970s, pragmatics has become the focus of interest not only in mainstream linguistics, but also in communication studies, discourse analysis (including applied studies in the schoolroom or courtroom), conversation analysis, in psychology, the social sciences, artificial intelligence, and in the study of language and cognition. The study of language has therefore gradually widened its scope during the last half of the 20th century, from the *sign* to the use of signs in social situations, and from the *sentence* to the use of utterances in context.

Half a century after widening the scope of linguistics in this way, it has, however, become clear that a wider pragmatic perspective on language, social interaction, and mind had, in fact, already existed well before Austin made it popular in the 20th century (Nerlich and Clarke, 1996, 2000, where more references can be found) (*see* **Pragmatic Acts**).

This history of pragmatics will concentrate on uncovering the roots of the *different approaches to pragmatics* that one can distinguish in Europe and America: (1) the Anglo-Saxon approach which emerged from *ordinary language philosophy* with Wittgenstein, Austin, and Searle, and which has dominated the field, and which (2) developed concurrently with, but independent of, the school of *British contextualism and functionalism*; (3) the French approach, which is based on the *theory of enunciation* elaborated by Émile Benveniste; (4) the German approach (associated with the *critical theory movement* around Jürgen Habermas and Karl Otto Apel), which wants to study pragmatics as part of a general theory of (communicative) action.

These European traditions of pragmatic thinking were affiliated in various ways with the development of *pragmatism* as a new philosophy that emerged in the United States in the latter part of the 19th century, and which made the three-way split between syntactics, semantics, and pragmatics popular in linguistics, philosophy, and semiotics.

All approaches, the two Anglo-Saxon ones, the French one, the German one, and the American one, have their deeper roots in Antiquity, that is, in *rhetoric*. They are also all based, to various degrees, on Immanuel Kant's philosophy of the 'active (transcendental) subject' and on John Locke's philosophy of the 'semiotic act.'

These pragmatic modes of thought can be studied as *historical traditions*, but they can also be analyzed as *theoretical frameworks* that cluster around certain pragmatic key words:

1. Anglo-Saxon: speech act, meaning, use; meaning, intention, context, function
2. German: agenthood of (transcendental) subject, dialogue, pronouns
3. French: subjectivity, markers of subjectivity, indexicals
4. American: meaning as action, the triadic sign relation.

These four traditions should not be regarded as monolithic, unchanging, and exclusive. Since the 1970s, many approaches have developed that deal with language in use, such as, to mention just a few, the social pragmatics developed by Jacob Mey (Mey, 2001), also called *language in use* theory, the systemic-functional approach to language developed by Michael A. K. Halliday (Halliday, 1978), the various types of (critical) discourse analysis (see Mey, 1979, 1985; Beaugrande, 1996), and more recently the pragmatic and critical approach to metaphor analysis one could call the theory of *metaphor in use*.

Sources of Antagonism and Inspiration

It is generally assumed that language was studied as an *organism* in the 19th century and as a *system* in the 20th. This does not seem to leave much room for the study of language in use or in context or the study of the relationship between language and action. However, looking at disciplines adjacent to linguistics, such as various kinds of philosophy, psychology, sociology, and semiotics, one can discover that the roots of pragmatic thinking go back as far as the 19th and early 20th centuries. Inasmuch as these disciplines influenced the fringes of official linguistics, they also triggered pragmatic insights in linguistic thinking itself, especially in its reflection on meaning.

Those linguists who were interested in the meaning and use of language and not only, like the majority of their historical-comparative colleagues, in sound change, turned to an older source of pragmatic inspiration: rhetoric. Since antiquity, and since the Middle Ages as part of the trivium (rhetoric, grammar, logic), rhetoric had been part and parcel of language studies. However, in their efforts to constitute linguistics as an autonomous science, historical-comparative linguists had focused almost exclusively on the study of grammar, detaching it from the study of language in discourse (rhetoric) and from logic. By contrast, in their study of meaning and discourse, linguists and philosophers not working in the mainstream of historical-comparative linguistics made use of some of the concepts inherited from rhetoric (as for example the figures of speech, the situation of discourse, the interaction between speaker and hearer, and the

tripartition of grammar, logic, and rhetoric itself, which is at the root of many semiotic triads).

Among those who redefined and criticized the use of the concept of organism as a metaphor for the study of language, many also rejected an older philosophical theorem, namely that language represents thought (or ideas) and that only language that represents thoughts or the world is worthy of philosophical inquiry, as Aristotle had claimed in *De Interpretatione*, 17a, 1–5 (see Whitaker, 1996).

For pragmatic thinkers of all times, by contrast, language is not only there to represent true or false states of affairs, but it is used to influence others in specific ways, to communicate with others, to act upon others, and to make them act in certain ways, in other words, to change the world. This is why Austin later rejected the philosophy of language developed by those logical positivists who paid lip service to pragmatics, but still only studied statements as mapping onto states of affairs and the understanding of statements as the understanding of truth conditions. For some of the early pragmaticians, as well as for the later ones, language was also not simply a system of conventional signs for the representation of thoughts. They reflected instead on the motivation underlying the signs' sound-structure and meaning, on the 'naturalness' of language, as one would say now, and on the sources of that motivation in the speakers and the speech situation, in the uses they make of signs in situations.

Early Pragmatic Insights

In Germany, the representational theory of language was undermined in the tradition of Kant, whose theory of the active organizing powers of the mind gave the impetus for a philosophy of language based on the mental acts of the speaker/hearer, especially in the works of Johann Severin Vater, August Ferdinand Bernhardi, and Wilhelm von Humboldt, published during the first two decades of the 19th century. These thinkers gradually replaced the philosophical study of the subject-object relation by a linguistic study of the subject-subject relation, and, in doing so, they developed a dialogical approach to language. The following quote from Vater's work, in which he develops a pragmatic conception of the sign (influenced by Locke's semiotics and Johann Heinrich Lambert's philosophy of language), will demonstrate this tradition, which ends with Humboldt's study of dialogue (for more information on the Kantian tradition, see Perconti (1999).

> One can define these concepts [the sign, etc.] from the following points of view: (1) the one who signifies, (2) the one for whom one signifies, (3) the purpose of the signification, (4) the success, the reciprocation of this purpose, (5) the sign, as the means, and (6) that which is signified (Vater, 1801: 137; all translations are Nerlich's).

Compare with Humboldt:

> It is particularly relevant to language that duality has a much more important role in it than anywhere else. All speech is based on interlocution (*Wechselrede*), in which the speaker always posits the addressee as the one person opposite him, even when there are more people around. [. . .] To divide humanity into two classes, the natives and the enemies, is the basis of all primitive social bonding (Humboldt, 1963 [1827]: 137–138).

During the second half of the 19th century, the German pragmatic tradition focused even more on the role of the hearer and on language understanding in situation, possibly under the influence of the hermeneutical tradition (from Friedrich Schleiermacher to Wilhelm Dilthey).

In England, the representational theory of language was overthrown in the writings of the Scottish school of common sense philosophy, in particular the work of Thomas Reid. Reid remarked that Aristotle had been right to observe that

> besides that kind of speech called a *proposition*, which is always either true or false, there are other kinds which are neither true nor false, such as a prayer or a wish; to which we may add, a question, a command, a promise, a contract, and many others (Reid, 1872, vol. II: 692).

However, according to Reid, Aristotle had been wrong in relegating the study of these speech acts other than the proposition to rhetoric (or to the domain of what is now called the pragmatic 'wastebasket' (see Mey, 2001: 12–15):

> The expression of a question, of a command, or of a promise, is as capable of being analyzed as a proposition is; but we do not find that this has been attempted; we have not so much as given them a name different from the operations which they express (Reid, 1872, vol. I: 245).

Reid therefore developed a philosophical theory of meaning and a theory of speech acts that could accommodate these types of sentences. He stressed that, unlike statements, these other sentences are fundamentally 'social operations,' because their success necessarily depends on their uptake by others. Reid's views on language spread widely, from Scotland to England, mainly Cambridge, to the United States, and to France.

Whereas Reid had mainly focused on speech acts as social acts and thus contributed to speech-act theory *avant la lettre*, the philosopher and elocution teacher Benjamin Humphrey Smart developed a contextualist

theory of meaning as his contribution to a general theory of signs and to early pragmatics. In his *Outline of sematology: or an essay towards establishing a new theory of grammar, logic, and rhetoric* (Smart, 1831), Smart took up Locke's threefold division of knowledge into (1) *physicology*, or the study of nature, (2) *practology*, or the study of human action, and (3) *sematology*, the study of the use of signs for our knowledge, or, in short, the doctrine of signs (Smart, 1831: 1–2). His study deals with signs "which the mind invents and uses to carry on a train of reasoning independently of actual existences" (Smart, 1831: 2). For Smart, sematology (as later semiotics for Morris, and going back to the medieval trivium) had three parts: grammar, logic, and rhetoric. In all three parts, Smart makes it clear that signs do not *mean* ideas, they are *used* to mean something in *context*. He quotes the following passage from the work of the Scottish common sense philosopher Dugald Stewart, a follower of Reid:

> our words, when examined separately, are often as completely insignificant as the letters of which they are composed; deriving their meaning solely from the connection, or relation, in which they stand to others (Stewart, 1854–1860, V: 154–155).

Smart was widely read, although it seems more by thinkers working outside linguistics proper, such as Charles Darwin. The term Smart used for his philosophy of language in context, *sematology*, was later used idiosyncratically by the German psychologist Karl Bühler, but Smart's theory of signs as part of his epistemology was also continued, to some extent, by those working in the tradition of 'significs' (see more on significs below).

Locke and the opposition to Locke were also important in France. Etienne Bonnot de Condillac and the Ideologues had based their philosophy of language in part on Locke's representationalism and empiricism, and saw in language a system of signs for the representation of ideas and sensations. After the French Revolution, in which the Ideologues had been involved, and during the French Restoration, their sensualist (and therefore quasi-materialist) philosophy of language was attacked by French philosophers and psychologists of the eclectic school, such as Victor Cousin, Théodore Jouffroy, and also Maine de Biran, who drew on ideas taken from Kant's philosophy of the active spirit, as well as from the common sense philosophers in Scotland and England, such as Reid. Based on their theories and Reid's conception of social acts, Adolphe Garnier formulated, about 1850, a theory of speech acts (orders and promises, for example) which highlighted the social aspects of speech acts, that is, both the interaction between (the intention of) the speaker and (the understanding by) the hearer, and the interlocutors' social position in the context of discourse. However, Garnier's speech-act theory went almost unnoticed. It was only at the beginning of the 20th century that the legal philosopher Adolf Reinach formulated a similar, but much more elaborate, theory of speech acts, or what Reinach called, with Reid, *social acts*, based, in part, on Edmund Husserl's phenomenology. For Reinach, speech acts, such as commands, can only exist *qua* command insofar as they are not divided up into a statement or *constatation* and its performance. They are both part of *the social act* (Reinach, 1913: 708; Engl. transl. 1983: 20), similar to what Jacob Mey (Mey, 2001: 206–235) later called *pragmatic acts* (*see* **Speech Acts; Pragmatic Acts**).

The Development of Pragmatics between 1850 and 1930

Gradually, Cousin's philosophy was replaced in France by Hippolyte Taine's rationalist and positivistic psychology. In Germany, too, psychology, especially Friedrich Herbart's mathematical psychology, became more important than philosophy for the advancement of the study of the nature of language. Herbart himself proposed that language could only be understood in the context of human action in general; a view repeated (without direct reference to Herbart, but totally in his spirit) by William Dwight Whitney in the United States (who also stressed the social dimension of language as an institution), by Johan Nicolai Madvig in Denmark (who stressed the role of context and developed a theory of meaning as use), and by Philipp Wegener in Germany who studied not only language in context but also what he called the *dialogic speech-act*, and what H. P. Grice was later to call *conversational implicatures* (*see* **Implicature, Grice, Herbert Paul (1913–1988)**). Wegener analyzed, for example, (elliptical) 'statements' that function as commands:

> In the word-sentence 'my boots', the pure word-image does not trigger the representation of the facts that (1) somebody orders an action; (2) what that action is; (3) who should execute the action. All this can only be inferred from the situation and the gestures. The word-image only evokes the representation of a definite thing that the speaker has in mind as an object (Wegener, 1921: 9–10).

Heymann Steinthal, another follower of Humboldt and Herbart, and one of the most famous psychologists of language in the 19th century (read and criticized by Madvig, Whitney, Wegener, and many others), did not directly contribute to a pragmatic

theory of language, but, inspired by Steinthal's work and the Russian linguist Aleksandr A. Potebnya, developed an original theory of language and meaning based on the concept of psychological activity. (For the Russian tradition, especially Voloshinov and Bakhtin, see Nerlich (2000). *See also* **Voloshinov, V. N. (ca. 1884/5–1936); Bakhtin, Mikhail Mikhailovich (1895–1975).**)

In France, Taine's call *back to Condillac*, and his semiotic theory of signs, was heard by the linguist Michel Bréal who abhorred the widely used metaphor according to which words or meanings 'live and die' like biological organisms. Instead, he argued that

> Our forefathers of the school of Condillac, those ideologists who for 50 years served as target to a certain school of criticism, were less far from the truth when they said, in simple and honest fashion, that words are signs. [. . .] *Words are signs*: they have no more existence than the signals of the semaphore, or than the dots and dashes of Morse's telegraphy (Bréal, 1964 [1900]: 249, italics ours).

However, Bréal did not only study language as a system of signs, but also as the expression of the speaking subject, who uses language to express emotions, beliefs, wishes, and demands, that is, to accomplish speech acts. He also analyzed the traces left in speech of the speaker using language, as for example the function of markers such as *nevertheless*, *hopefully*, etc. Furthermore, like Reid and others, Bréal criticized what Austin later called the *descriptive fallacy* in linguistic thinking. Compare:

> Language is not only made to say: 'the sun shines on the countryside', 'the rivers flow into the sea'. Beyond that, language serves mainly to give expression to desires, demands, to be the expression of the will. It is this *subjective* side of language that should be studied more [. . .] (Bréal, 1877: 361–362).

The topic of the subjectivity in language was taken up by the French counterpart to Anglo-Saxon speech-act theory, viz., the theory of enunciation, as elaborated by Charles Bally, Gustave Guillaume, and Émile Benveniste and amalgamated with a theory of speech acts in the work of Oscar Ducrot. These French linguists also studied what they called the actualization of language (*la langue*) in speech (*parole*) through what Roman Jakobson, for example, called *shifters*, and Bally called *indicators*.

But Bréal not only initiated a study of subjectivity and indexicality in language, but also promoted a functionalist approach to language. Quite early on in his career, while actually introducing German historical-comparative linguistics to France, Bréal began to criticize its organicism and its way of studying linguistic forms without taking into account their function. For Bréal, as for other 'functionalists' of that time (such as Wegener), function was the primary force of language change. Forms do not change in sound or meaning all by themselves, but because they are used with a specific function by the language user in discourse and in a certain situation. Other French functionalists were the psychologists Frédéric Paulhan and Henri Delacroix, and the linguist and medical doctor Eugène Bernard Leroy. Paulhan, in particular, established an explicit theory of speech acts in the context of a theory of linguistic functions that is directly comparable to that developed by Karl Bühler in Germany (more on Bühler below). Using an example that has become commonplace in pragmatic writing, he points out that:

> [I]n order to understand the words 'it's raining', it suffices that, consciously or half-consciously, I take my umbrella with me when I want to go out. If I act in this way, I can really say that I have understood the words 'it's raining', even though I might not have associated them with any images that they represent (Paulhan, 1886: 47).

The German functionalists and speech-act theorists *avant la lettre* at the turn of the 19th to the 20th century, especially Anton Marty and Bühler, were influenced by rationalist linguists such as Whitney, Madvig, Wegener, and Bréal on the one hand, but also, on the other, by new developments in psychology, such as the descriptive psychology developed by Franz Brentano, by the psychology of Gestalt, by phenomenological psychology, as well as by developments in social behaviorism.

Bühler (who was also a great admirer of Wegener) was working in the context of the Würzburg school of psychology, and he knew the work of Marty and Edmund Husserl well. He established the most elaborate theory of pragmatics in Germany (Bühler, 1934), of which his 'organon model' was the central part. In this model, he places the linguistic sign in its context of use, bringing into the model the speaker and hearer (forgotten in the semiotic triangle popularized by Charles K. Ogden and Ivor A. Richards) and the reference to 'things' (forgotten in Ferdinand de Saussure's famous speech circuit). The organon model, depicted by a triangle overlaid upon a circle, shows that every sign is at one and the same time a symptom (indicator, index) by virtue of its dependence on the sender (whose internal state it expresses), a signal by virtue of its appeal to the recipient (whose behavior it controls), and a symbol by virtue of its assignment to the objects and states of affairs (to which it refers). And so, every sentence is at one and the same time *expression*, *appeal*, and *representation*.

These are also the three main functions of language and sign use.

This functional and semiotic theory of language was further elaborated by linguists, such as Erwin Koschmieder and Alfons Nehring, as well as by philosophers, such as Karl-Otto Apel and Jürgen Habermas. Koschmieder, also influenced by Husserl, developed one of the first theories of performatives in Germany, a theory which can be directly compared to that which was being developed on the other side of the English Channel by Austin.

As early as 1929, Koschmieder had hinted at some puzzling syntactic phenomena of tense and aspect which would lead him to postulate a new "case of coincidence" (Koschmieder, 1965 [1945]: 26–27). He discussed the Hebrew equivalent of the sentence *I hereby bless him*, and pointed out that in such examples the action arises in the very utterance, that is to say: action and utterance coincide. He also used the example (later made famous through Austin): *Hiermit eröffne ich die Versammlung* ('I hereby open the meeting', i.e., 'I declare the meeting to be opened'), and he pointed out that *Hiermit schreibe ich einen Brief* ('I am hereby writing a letter') is impossible.

A Cambridge psychologist, George Frederick Stout, working toward the end of the 19th century, was also influenced by Brentano, as well as by Herbart and by Kant. From Kant, he took the insight into the active organizing powers of the individual in understanding the world and applied it to the individual using language. Stout was opposed to English associationism as proposed for example by Alexander Bain (Bain, 1855) and John Stuart Mill, and put forward a contextualist theory of language that incorporated some principles reminding one of the later Gestalt school of psychology. He was especially interested in the context-sensitivity of the notions of subject and predicate, thereby implicitly challenging linguistic analysis in terms of logic alone. He thus contributed to the development of ordinary language philosophy in Cambridge.

The psychological work of Paulhan and Stout was appreciated by the English philosopher and philanthropist Lady Victoria Welby, whose work on "meaning" (which she called *significs*) started an English and a Dutch school of pragmatics (named 'significa'), in which not only was context important, but language use and the whole speech event (including the speaker's intention and the hearer's interpretation) were taken into account (see Schmitz, 1990).

The English school of contextualism (Sir Alan Henderson Gardiner, Bronisław Malinowski, John Rupert Firth) was partly based on the work of Welby (just as later also was Ogden and Richards' work, who, too, can be counted among the functionalists) on the one hand, and on the work of Wegener (which was much less metaphysical and more 'pragmatic' than Welby's) on the other. Gardiner wanted to analyze "acts of speech," Firth whole "speech events," and Malinowski wanted to study meaning as action. In his famous supplement (on meaning in primitive languages) to Ogden and Richard's book *The meaning of meaning*, Malinowski claimed that language is "a mode of action," especially of cooperation between people (Malinowski, 1923: 315).

The meaning of meaning also contained an extract of Peirce's work on semiotics as a direct result of Lady Welby's influence. In the early years of the 20th century, Lady Welby had corresponded with the father of pragmatism and semiotics, the American philosopher Charles Sanders Peirce. Peirce had inherited the term *pragmatisch* from Kant (in the latter's distinction between *practical* reason, that is, of the 'pure kind,' and *pragmatic* reason, that is, of the 'empirical' kind), and he knew the semiotic literature of the past well, from the Medieval philosopher Peter of Spain to Locke, Reid, and Welby. His counterpart, the pragmatist psychologist William James, by contrast, derived the term *pragmatism* from the Greek *prágma*, meaning 'practice', 'action'. And, whereas Peirce's *pragmaticism* (a term Peirce introduced to set his theory off against James's) became part of his semiotics, as a general theory of signs and of meaning, James's *pragmatism* became part of a morally based psychology and theory of truth (*see* **Peirce, Charles Sanders (1839–1914)**).

Inspired in part by some principles of pragmatism, but also by Ogden and Richards' theory of signs and symbols, as well as by developments in logical positivism and behaviorism, the American Charles Morris is well-known for his tripartition of semiotics into *semantics*, as the study of the relationship between words and the world, *syntactics*, as the study of the relationship between words and words, and *pragmatics*, as the study of the relationship between words and their users (Morris, 1938). He made this the basis for a behavioristic type of semiotics.

The problem of 'meaning,' so important to Lady Welby and the pragmatists, became the focus of philosophical thinking worldwide. This was especially the case in England where, from the turn of the 19th century until the mid-20th century, it was leading up to the 'linguistic' and then 'pragmatic' turns in the philosophy of language. Initially, philosophers, such as the Oxford philosopher and classical scholar Austin, used linguistic analysis to find philosophical clarity; later, linguists used philosophical methods, such as those advocated by Austin, to study wider aspects of language. Here one can trace a line of thought leading from Gottlob Frege to Russell and

the early Ludwig Wittgenstein (Wittgenstein I), to the later Wittgenstein (Wittgenstein II), Gilbert P. Ryle, Peter F. Strawson, Austin, H. Paul Grice, and finally to John Searle. Searle had written his Oxford D.Phil. thesis under Austin and Strawson on Frege's notion of sense and reference, and his concept of 'illocutionary force,' so central to pragmatics, can be traced back to Frege.

Pragmatism, Semiotics, and Speech Act Theory

As we have seen, many psychologists, philosophers, and linguists shared what Malinowski once called a "pragmatic *Weltanschauung*" (Malinowski, 1923: 328) at the turn of the 19th into the 20th century. They all regarded language as a mode of action and interaction. This conception was not unknown to Austin, who had read Gardiner, Morris, Peirce, and others. However, it seems that Austin neither wished to be associated with the contextualist-functionalist pragmatics developed on his doorstep (Nerlich, 1996), nor with the pragmatist, behaviorist, and semiotic pragmatics developed on the other side of the Atlantic by Morris, nor with the formal type of pragmatics developed by ideal language philosophers such as Rudolf Carnap. Austin also did not accept Morris's tripartition of semiotics into syntactics, semantics, and pragmatics; as he pointed out in 1940:

> Now the reason why I cannot say 'the cat is on the mat and I don't believe it' is not that it offends against syntactics in the sense of being in some way "self-contradictory." What prevents me saying it, is rather some semantic convention (implicit, of course), about *the way we use words in situations* (Austin, 1963 [1940]: 10; italics ours).

And,

> the supposed "ideal" language . . . is in many ways a most inadequate model of an actual language: its careful separation of syntactics from semantics, its list of explicitly formulated rules and conventions, and its careful delimitation of their spheres of operation – are all misleading. An actual language has few, if any explicit conventions, no sharp limits to the spheres of operation of rules, no rigid separation of what is syntactical and what semantical. (Austin, 1963 [1940]: 13).

It is astonishing to see that Austin does not use the term *pragmatics* in this context, as he implicitly argues for an integration of syntactics and semantics into pragmatics, being the study of the use of words or signs in the situation of a speech act.

Conclusion

Before Austin, the foundations for pragmatics had been laid by thinkers who stressed that:

- Signs are not only used for the expression of thought, but have various other functions.
- Signs have not only an intellectual but also an affective function.
- Sign use has basically three functions: representation, expression, and appeal.
- Signs can only be understood in the context of the situation in which they are used.
- Speaking is a goal-directed action.
- Signs are instruments used in the act of speech, and their use has practical effects and consequences.
- Signs are mainly used to influence others.
- Signs only function in dialogue and conversation; the reciprocity between speaker and hearer is important.
- Signs are used for the coordination of human behavior.
- Some signs are indexically linked to reality and the language users.

Rather late in the development of pragmatics are these ideas:

- Certain speech acts are self-referential.
- In saying something we are doing something.

Pragmatics: Linguistic Imperialism

R Phillipson, Copenhagen Business School, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

The study of linguistic imperialism focuses on how and why certain languages dominate internationally, and on attempts to account for such dominance in an explicit, theoretically founded way. Language is one of the most durable legacies of European colonial and imperial expansion. English, Spanish, and Portuguese are the dominant languages of the Americas. In Africa, the languages of some of the colonizing powers, England, France, and Portugal are more firmly entrenched than ever, as English is in several Asian countries.

The study of linguistic imperialism can help to clarify whether the winning of political independence led to a linguistic liberation of Third World countries, and if not, why not. Are the former colonial languages a useful bond with the international community and necessary for state formation and national unity internally? Or are they a bridgehead for Western interests, permitting the continuation of a global

Pragmatics: Linguistic Imperialism

R Phillipson, Copenhagen Business School, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

The study of linguistic imperialism focuses on how and why certain languages dominate internationally, and on attempts to account for such dominance in an explicit, theoretically founded way. Language is one of the most durable legacies of European colonial and imperial expansion. English, Spanish, and Portuguese are the dominant languages of the Americas. In Africa, the languages of some of the colonizing powers, England, France, and Portugal are more firmly entrenched than ever, as English is in several Asian countries.

The study of linguistic imperialism can help to clarify whether the winning of political independence led to a linguistic liberation of Third World countries, and if not, why not. Are the former colonial languages a useful bond with the international community and necessary for state formation and national unity internally? Or are they a bridgehead for Western interests, permitting the continuation of a global

system of marginalization and exploitation? What is the relationship between linguistic dependence (continued use of a European language in a former non-European colony) and economic dependence (the export of raw materials and import of technology and know-how)? In a globalizing world, has English shifted from serving Anglo-American interests into functioning as an instrument for more diverse constituencies? Or does U.S. dominance in the neoliberal economy constitute a new form of empire that consolidates a single imperial language?

Imperialism has traditionally been primarily concerned with economic and political aspects of dominance (Hobson, 1902). Later theorists have been concerned with analyzing military, social, communication, and cultural activities, and the underlying structures and ideologies that link powerful countries, the 'Center,' with powerless countries, the 'Periphery,' and the structure of exploitation from which rich countries benefit and poor countries suffer (Galtung, 1980). Resources are distributed unequally internally within each country, which has its own Center and Periphery, which in Marxist analysis is seen in terms of class (Holborrow, 1999) (*see* **Class Language**). Linguistic imperialism was manifestly a feature of the way nation-states privileged one language, and often sought actively to eradicate others, forcing their speakers to shift to the dominant language. It was also a feature of colonial empires, involving a deeper degree of linguistic penetration in settler countries (e.g., Canada, New Zealand) than in exploitation and extraction colonies (e.g., Malaya, Nigeria). Linguistic imperialism presupposes an overarching structure of asymmetrical, unequal exchange, where language dominance dovetails with economic, political, and other types of dominance. It entails unequal resource allocation and communicative rights between people defined in terms of their competence in specific languages, with unequal benefits as a result, in a system that legitimates and naturalizes such exploitation (Phillipson, 1992) (*see* **Minorities and Language** and **Linguistic Decolonization**).

Linguistic imperialism can be regarded as a subcategory of cultural imperialism, along with media imperialism (e.g., news agencies, the world information order), educational imperialism (the export of Western institutional norms, teacher training, textbooks, etc., and World Bank policies privileging Center languages in education systems; Mazrui, 2004), and scientific imperialism (e.g., dissemination of paradigms and methodologies from the Center, which controls knowledge about the Periphery). Linguistic imperialism may dovetail with any of these, as for instance when English as the dominant language of science marginalizes other languages, English as 'Lingua Tyrannosaura' (Swales, 1997; Ammon, 2001; Phillipson, 2002).

The mechanisms of linguistic imperialism are documented in works that link linguistics with colonialism (Calvet, 1974 refers to linguistic racism, confirming the interlocking of 19th century philology with European racist thought), relate the promotion of English in educational 'aid' to the economic and political agendas of Center countries (Phillipson, 1992), and discuss the effect of literacy on the local language ecology, including the role of missionaries (Mühlhäusler, 1996). Linguistic dominance has invariably been buttressed by ideologies that glorify the dominant language: as the language of God (Arabic, Dutch, Sanskrit), the language of reason, logic, and human rights (French over several centuries), the language of the superior ethnonational group as advocated by (imperialist racism, German in Nazi ideology), the language of modernity, technological progress, and national unity (English in much postcolonial discourse). A Ghanaian sociolinguist describes linguistic imperialism as

> the phenomenon in which the minds and lives of the speakers of a language are dominated by another language to the point where they believe that they can and should use only that foreign language when it comes to transactions dealing with the more advanced aspects of life such as education, philosophy, literature, governments, the administration of justice, etc. . . . Linguistic imperialism has a way of warping the minds, attitudes, and aspirations of even the most noble in a society and preventing him from appreciating and realizing the full potentialities of the indigenous languages (Ansre, 1979: 12).

There are studies that focus on the discourses accompanying linguistic hierarchies (Pennycook, 1994), and the ambivalent role of English in contemporary India (Rajan, 1992). English in Africa is seen as "an imperial language, the language of linguistic Americanization, a language of global capitalism, . . . creating and maintaining social divisions serving an economy dominated primarily by foreign economic interests and, secondarily, by a small aspiring African bourgeoisie" (Mazrui, 2004: 30, 40, 52), though English is simultaneously appropriated for Afrocentricity in Africa and in the United States. The tension between the need to learn English for local empowerment alongside local languages, and the adequacy of our theories for addressing these issues has been explored (Canagarajah, 1999, several contributions in Ricento, 2000) (*see* **Power and Pragmatics**).

Fishman *et al.* (1996) is an anthology on *Post-Imperial English: Status Change in Former British and American Colonies, 1940–1990*, with contributors

from many countries, who were asked to assess linguistic imperialism in each context. The editors see the need for English to be "reconceptualized, from being an imperialist tool to being a multinational tool . . . . English . . . being postimperial (as the title of our book implies, that is in the sense of not directly serving purely Anglo-American territorial, economic, or cultural expansion) without being postcapitalist in any way." Fishman, in a 'summing-up and interpretation' of the contributions to the book, correlates the status of English with hard data on the use of English in the media, education, studies abroad, technology, administration, etc., and more subjective assessments. He tabulates the degree of 'anglification' in each state. His assessment is that the "socioeconomic factors that are behind the spread of English are now indigenous in most countries of the world" and that the continued spread of English in former colonies is "related more to their engagement in the modern world economy than to any efforts derived from their colonial masters" (1996: 639). Fishman seems to ignore the fact that 'engagement in the modern world' means a Western-dominated globalization agenda set by the transnational corporations, the International Monetary Fund, and the World Trade Organization, with the U.S. military intervening whenever 'vital interests' are at risk. Although some contributors conclude that linguistic imperialism is not present, they have no difficulty in using the concept in country studies, and none question its validity or utility.

Others are more robust in distancing themselves from a linguistic imperialism approach, when reassessing the language policies of the colonial period and in theorizing about the role of English in the modern world (Brutt-Griffler, 2002) and when describing the global constellation of languages (de Swaan, 2001), on which see Phillipson (2004). English plays a supremely important role in the ongoing processes of globalization, which is seen by some scholars as synonymous with Americanization. English is playing an increasingly prominent role in continental European countries and in the institutions of the European Union, though in principle and law these are committed to maintaining linguistic diversity and the equality of the languages of the member states (Phillipson, 2003). Increased European integration and market forces are, however, potentially leading to all continental European languages becoming second-class languages. This concern has led to the advocacy of Europe-wide policies to strengthen foreign language learning, but few European states (probably Sweden and Finland are those most active) have elaborated language policies to ensure the continued strength of national languages alongside competence in English and full respect for linguistic human rights (*see* **Linguistic Rights**).

One symptom of market forces is the major effort by 'English-speaking' states to expand their intake of foreign students. Higher education is increasingly seen as a market opportunity, a sector that the British government seeks to expand by 8 per cent per year between 2004 and 2020. The British economy benefits by £11 billion directly and a further £12 billion indirectly (British Council). Over half a million foreign students attend language schools in Britain each year. The English Language Teaching business is of major significance for the British economy. These figures reveal something of the complexity of the supply and demand elements of English as a commodity and cultural force. They also demonstrate the need for the analysis of linguistic dominance to shift from a colonial and postcolonial perspective to contemporary patterns that are maintained by more subtle means of control and influence, language playing an increasingly important role in the internationalization of many domains.

Thus in the teaching and marketing of 'communication skills,' a shift from linguistic imperialism to communicative imperialism can be seen: "Language becomes a global product available in different local flavours . . . . The dissemination of 'global' communicative norms and genres, like the dissemination of international languages, involves a one-way flow of expert knowledge from dominant to subaltern cultures" (Cameron, 2002: 70). A focus on communication skills may well entail the dissemination of American ways of speaking and the forms of communication, genre, and style of the dominant consumerist culture, which globalization is extending worldwide (*see* **Intercultural Pragmatics and Communication**).

In *Empire*, Hardt and Negri (2000) draw together many threads from political, economic, and cultural theory and philosophy, and astutely unravel the role of communication in global social trends, and the ways in which language constitutes our universe and creates subjectivities. They reveal how the hegemonic power imposes or induces acceptance of its dominion. They show why it has been so important for the corporate world not only to dominate the media but also education, which is increasingly run to service the economy and to produce consumers rather than critical citizens. Linguistic dominance as such is not pursued in their book, and it is also largely neglected in social and political science. Linguistic imperialism, or linguistic dominance in the sense of the maintenance of injustice and inequality by means of language policies, is invariably connected to policies in commerce, science, international affairs, education,

culture, and the media, all of which involve material resources and attitudes, and all of which evolve dynamically.

Pragmatics: Optimality Theory

H Zeevat, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Optimality theory (OT) starts from the idea that the products of linguistic behavior are optimal with respect to a set of criteria for a certain task. The products can be pronunciations, language expressions, recognitions (of pronounced words), understandings (of, e.g., sentences or moves), the corresponding tasks being pronouncing a word, expressing a thought, recognizing a word, and understanding the contribution of an utterance. An important insight here is that optimality need not imply a perfect fit to the criteria – something which would be impossible in the (frequent) case of conflicting criteria.

A typical theme in OT phonology and syntax is precisely the conflict between various criteria, such as those enforcing economy vs. those enforcing expressivity (*see* **Phonology: Optimality Theory; Syntax: Optimality Theory**). A similar conflict in interpretation would be that between simplicity and stereotypicality on the one hand, and the need to interpret a given message completely and coherently on the other. These criteria are in conflict by their very nature and therefore, some of the criteria are (or may be) typically violated.

Criteria (such as constraints) can be implemented in neural nets, provided they are sufficiently simple (*see* **Constraint, Pragmatic**). The nets can be combined to select optimal solutions. In OT, the combination is done by ranking the constraints and by settling the competition between candidates by giving full priority to the highest-ranking criterion. A candidate loses out to another candidate if there is a highest ranked constraint on which it does worse, while both candidates do equally well on all constraints that are ranked higher.

culture, and the media, all of which involve material resources and attitudes, and all of which evolve dynamically.

Pragmatics: Optimality Theory

H Zeevat, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Optimality theory (OT) starts from the idea that the products of linguistic behavior are optimal with respect to a set of criteria for a certain task. The products can be pronunciations, language expressions, recognitions (of pronounced words), understandings (of, e.g., sentences or moves), the corresponding tasks being pronouncing a word, expressing a thought, recognizing a word, and understanding the contribution of an utterance. An important insight here is that optimality need not imply a perfect fit to the criteria – something which would be impossible in the (frequent) case of conflicting criteria.

A typical theme in OT phonology and syntax is precisely the conflict between various criteria, such as those enforcing economy vs. those enforcing expressivity (*see* **Phonology: Optimality Theory; Syntax: Optimality Theory**). A similar conflict in interpretation would be that between simplicity and stereotypicality on the one hand, and the need to interpret a given message completely and coherently on the other. These criteria are in conflict by their very nature and therefore, some of the criteria are (or may be) typically violated.

Criteria (such as constraints) can be implemented in neural nets, provided they are sufficiently simple (*see* **Constraint, Pragmatic**). The nets can be combined to select optimal solutions. In OT, the combination is done by ranking the constraints and by settling the competition between candidates by giving full priority to the highest-ranking criterion. A candidate loses out to another candidate if there is a highest ranked constraint on which it does worse, while both candidates do equally well on all constraints that are ranked higher.

The simplest view on criteria is that there is a single set of criteria applying to all languages; on this view, the criteria basically belong to the psychological conditions of the tasks involved in speaking and understanding human language. Language production is made easier if one uses shorter, less complicated structures, whereas understanding is improved by the use of longer, more complicated structures. But since production should make understanding possible, production must produce enough structure to allow understanding. This idea is at the basis of an OT-oriented typology of languages, which assumes that all human languages have the same constraints and only differ in their ranking of these constraints).

Optimality Theory and Pragmatics

Pragmatics is an obvious area of application for OT. For instance, Grice's well-known conversational maxims are naturally understood as a set of criteria on utterances; as is likewise known from the pragmatics literature, such criteria maybe violated (*see* **Grice, Herbert Paul (1913–1988); Neo-Gricean Pragmatics; Maxims and Flouting**). Conflicts of this kind are natural, since, for example, it is impossible to give all the information that is required (by the maxim of quantity) and be maximally brief (as required by the maxim of manner). Treatments of presupposition tend to be formulated in terms of preferences or defaults to get correct (or more correct) solutions to the projection problem (*see* **Pragmatic Presupposition; Projection Problem**). In relevance theory, the aim of the hearer is to maximize the relevance of the interpretation, another optimizing problem (*see* **Relevance Theory**). Discourse coherence is often treated as a matter of degree, but, again, maximizing coherence in discourse interpretation is matter of enhancing optimality.

When we look at more specific tasks such as pronoun resolution, recognizing information structure, choosing between different readings of an expression, or deciding on the rhetorical relations prevalent in a piece of text, it turns out that most of the suggested solutions to these problems rely on defaults and heuristics. Being able to reduce all of these phenomena to a small set of simple optimality-theoretical constraints would carry with it a big descriptive and theoretical gain. In addition to the possibility of simplifying and unifying pragmatics, this would also provide more insight into the psychology of the pragmatic component of the grammar, and furthermore offer the perspective of efficient implementation of some important building blocks of future dialogue systems.

It is currently hard to see where a program of this kind would lead to, or, indeed, whether it is possible at all. In an OT perspective, pragmatics has a special status. First of all, it is often impossible to state constraints that are equally meaningful for the production and for the interpretation of a text, as the two processes move in opposite directions. This may have something to do with the tradition that thinks of pragmatics as an interpretive theory: interpretation follows a process of semantic interpretation, presumably realized by compositional means (*see* **Frege, Gottlob (1848–1925); Compositionality: Semantic Aspects**). Even though this approach is less popular nowadays (a semantics that operates independently of pragmatics becoming more and more problematic), in many areas of pragmatics it is still the preferred view: a path leading from form to interpretation. For example, the constraint that prefers to interpret a 'presupposition trigger' (*see* **Presupposition; Pragmatic Presupposition**) by identifying the presupposition with the content already present in the context (by way of resolution), rather than adding the presupposition to the content, as new material (by way of accommodation) does not put any restrictions on the form of the utterance (or on its relation to the input). Presupposition triggers seem to function just as adequately in a resolution as in an accommodation approach; the intended effect is the same in both cases.

In all these respects, OT pragmatics is quite different from OT phonology and OT syntax, which are both dominated by constraints on form. Perhaps even more important is the fact that there is no indication that pragmatic constraints need to be differently ranked to account for different languages. For this reason, pragmatics may continue to be called a universal discipline, in accordance with the requirements of a typological classification of languages.

An important exception here is the class of pragmatically relevant items in a language. These can be certain kinds of anaphoric pronouns (including semantically empty, purely morphological agreement-type anaphors; *see* **Deixis and Anaphora: Pragmatic Approaches; Pronouns**); the different ways in which coherent discourse structure is built up; the kind of particles and modal verbs that a language disposes of; or the aspectual distinctions that can be made in a particular language. These factors have an important influence on the interpretation of different kinds of morphological items such as pronouns; on how we infer the existence and nature of discourse relations; on the various ways of expressing politeness; and on the central pragmatic issue of conversational implicature (*see* **Discourse Semantics; Politeness; Implicature**).

The exception makes it necessary to consider both production and interpretation (cf. above). An important hypothesis here is that of 'bidirectionality,' originally put forward by Smolensky (1996) as the simple claim that there is a single system of constraints that operates in both directions, production and interpretation; however, since the candidates are at one time the set of possible forms, but at another time the set of possible interpretations, they compete in different venues. A form–meaning pair is strongly superoptimal if and only if, in their respective competitions, the meaning makes the form win and the form makes the meaning win. Limiting oneself to cases of superoptimal production and interpretation, one may end up with a system where forms lack a meaning (because all meanings are better expressed by other forms) and meanings cannot be expressed (because all forms have better meanings). A famous example is due to McCawley (1978), who observed that, whereas the unmarked sentence (1a) below can be used to express standard ways of murdering the sheriff, the marked form (1b) forces the interpretation that the murder was unusual (e.g., Bart killed him by plugging the barrel of his gun, thus causing the gun to explode).

(1a) Black Bart killed the sheriff.
(1b) Black Bart caused the sheriff to die.

Under 'strong superoptimality,' (1a) indeed pairs with the interpretation 'simple killing,' whereas (1b) cannot be used: it always (for reasons of economy) loses out to (1a) in the production competition, just as it always (again, for reasons of economy) loses out in the interpretation competition to the stereotypical meaning associated with (1a). This situation caused Blutner (2001) to propose an alternative, called 'weak superoptimality,' where a form–meaning pair is disqualified only if it loses out to another weakly superoptimal pair. In the example, (1a) does not lose out to any competitors, so it is (at least) weakly superoptimal. In contrast, neither (1a) with the nonstandard meaning, nor (1b) with the standard meaning, are (weakly or strongly) superoptimal: both lose out when competing with the superoptimal (1a) with the standard, nonmarked meaning. That makes (1b) with the marked meaning weakly superoptimal. Weak bidirectionality is thus able to associate marked meanings with marked forms and unmarked meanings with unmarked forms, and in this way seems able to provide an explanation of the phenomenon of iconicity (*see* **Iconicity**).

Bidirectionality is a near-straightforward formalization of Grice's theory of meaning, according to which successful communication rests on the speaker's grasping the hearer's intention and vice versa: the speaker needs to take the hearer's point of view in deciding what signal to produce, and the hearer needs to take the speaker's point of view in deciding what intention to attribute to the speaker. Bidirectionality has a similar direct relationship to the neo-Gricean reconstructions of Horn (1984) and Levinson (2000) (*see* **Neo-Gricean Pragmatics**); it is therefore not surprising that one of the areas in which the bidirectionality hypothesis holds out promises of success is precisely pragmatics.

As to the part played by the bidirectionality hypothesis in language description, there are some serious problems with both strong and weak bidirectionality (an overview is found in Beaver and Lee, 2003). Other bidirectional phenomena can be understood as conventionalizations arising in language evolution; often, bidirectionality is reduced to a role in the simulation of language evolution.

Pronouns

A first optimality-theoretical study on pronouns is Bresnan's (2001) exploration of pronominal typology (*see* **Pronouns**; **Logophoric Pronouns**). Reduced realizations such as weak and clitic pronouns or agreement markers (bound or zero pronouns) (*see* **Clitics**) represent the typologically marked case, whereas the full pronoun is typologically unmarked. Reduced pronouns associate with topical antecedents, full forms with nontopical antecedents. Beaver (2004) explored the potential of OT in pronoun resolution, or the task of finding the correct antecedent for pronouns. An influential and well-studied computational linguistic approach to this problem is the model called 'centering' (Grosz *et al.*, 1985 is the original source; for a recent, much changed version, see Strube and Hahn, 1999) (*see* **Anaphora Resolution: Centering Theory Approach**). Beaver (2004), using a small system of constraints, provided a faithful reconstruction of the centering algorithm and shows that a form of restricted bidirectionality must be assumed so that the resulting system may also be successful in the production direction. Another attempt at finding an optimal pronoun resolution algorithm (not restricted to a reconstruction of the centering algorithm) is due to Bouma (2003). Mattausch (2003) gave a reconstruction of the complementary distribution of pronouns and reflexives in the development of English and was able to use the method of evolutionary OT developed by Jaeger (2003) to reconstruct the various stages the English reflexive system passed through before reaching its modern form.

Presupposition

In their study of the German particle *wieder* ('again'), Blutner and Jaeger (1999) gave a quite simple and convincing OT-based reconstruction of the presupposition theory as formulated by Van der Sandt (1992) and Heim (1983) (*see* **Presupposition**). In either theory, there are two defaults or preferences. The first preference in both theories is to identify the induced presupposition in the context of the utterance; this is called resolution. The second default prefers to add the presupposition either to the global context (Heim) or to the highest accessible context, wherever this is possible (Van der Sandt); this is called accommodation. The reconstruction has the following steps: Consistence > Resolve > Do Not Accommodate > Strength. Consistence stipulates that the current utterance does not conflict with what is known already. Resolve asks for the presence of the presupposed information at an accessible position. Do Not Accommodate forbids the addition of the presupposed information, while Strength excludes interpretations that are informationally weaker than the ones already available.

The reconstruction in the OT system improves in several ways on the earlier theories. Do Not Accommodate prefers partial resolutions to full accommodations; it does not outlaw copying presuppositions. Strength often gives a better prediction of the accommodation site than is the case in Van der Sandt's (1992) original theory. In particular, Zeevat's (2002) reconstruction allows for the exploration of particles such as *too* and their exceptional behavior in accounts of presupposition: they do not allow (full) accommodation and are obligatory in the contexts where they occur. In order to explain the latter phenomenon, one needs a 'max(F) constraint' (similar to that known from OT phonology): certain contextual relations are obligatorily marked (*see* **Phonology: Optimality Theory**). By contrast, the other phenomenon seems to allow for a bidirectional explanation: Do Not Accommodate, in a bidirectional interpretation, excludes candidate expressions that force accommodations, whenever there is a simple alternative that means the same and does not force the accommodation. In the case of particles, the sentence without the particle is always such an alternative.

The Future

Pragmatics offers a rich field for potential developments in OT. Among the possible areas for optimization one could mention the intonational phenomena studied by Blutner (2001), De Hoop (2003), and Hendriks (2003); here, much remains to be done. Another area that is waiting for an OT treatment is that of discourse structure and discourse relations. The work done by Asher and Lascarides (2003), using a mixture of optimization and default logic, would benefit from the relative simplicity of the OT architecture. Very few people have so far tried to address implicatures and explicatures in this framework; explorations by Blutner (2001) and Krifka (2002) are quite promising, though. An important new strand of research is the investigation of language change by evolutionary simulation, based on systems of OT constraints. The reconstruction of pragmatics along the lines of bidirectionality is the central concept in these endeavors, which focus on an investigation of how systems reach stability under 'pragmatic pressure.'

The phenomena investigated so far have been relatively simple, though of fundamental importance. In a wider perspective, one may hope that some day, we may be able to account for the peculiarities of human language as they arise in linguistic evolution under the influence of pragmatic pressure. Such results may still be far away, but the investigation of pragmatic problems in the light of optimality theory has laid some of the groundwork for this enterprise.

Introduction

Traditionally, pragmatics has been considered as forming a triad with syntax and semantics (a partition originally ascribed to Charles Morris, and inspired by ideas from the philosopher Charles S. Peirce). Here, syntax is considered to be the study of the formal relations of one sign to another, while semantics studies the relations of signs to objects in the outside world. Finally, pragmatics is thought of as the relation of signs to those who interpret the signs, the users of language (Morris, 1938: 6). It is the latter part of Morris' definition that will be the guiding point of this article; however, the original restriction to signs will be relaxed, such that we now speak of communication in a very broad sense, also including nonverbal means such as gestures and body movements. The emphasis of this modern study of pragmatics is, as it was for Morris, on the user; however, the user is not thought of here as an isolated individual, but as a social animal in the Aristotelian sense: a being that is dependent on the context in which she or he lives, but at the same time is able to interact with and change that context through the use of signs – read: human language and other human communicative means.

Understanding and Misunderstanding

People talk in order to communicate. Good communication happens when speakers understand each other correctly, that is, in accordance with what the speaker means and the hearer understands the speaker to mean. When such an understanding does not occur, the communicative situation becomes one of misunderstanding rather than of understanding.

Many people (including most linguists) believe that communication, and hence understanding, depends solely on the words spoken. The famous reply to a journalist's question, "Read my lips," attributed to former U.S. President George H. W. Bush, expresses a belief in the validity of the verbal utterance as proffered by a speaker, without regard either to what the speaker may have had in mind or to the actual circumstances of the speaking and reading.

Another widespread error is made by people who believe that human communication should obey

Pragmatics: Overview

J L Mey, University of Southern Denmark, Odense, Denmark

Introduction

Traditionally, pragmatics has been considered as forming a triad with syntax and semantics (a partition originally ascribed to Charles Morris, and inspired by ideas from the philosopher Charles S. Peirce). Here, syntax is considered to be the study of the formal relations of one sign to another, while semantics studies the relations of signs to objects in the outside world. Finally, pragmatics is thought of as the relation of signs to those who interpret the signs, the users of language (Morris, 1938: 6). It is the latter part of Morris' definition that will be the guiding point of this article; however, the original restriction to signs will be relaxed, such that we now speak of communication in a very broad sense, also including nonverbal means such as gestures and body movements. The emphasis of this modern study of pragmatics is, as it was for Morris, on the user; however, the user is not thought of here as an isolated individual, but as a social animal in the Aristotelian sense: a being that is dependent on the context in which she or he lives, but at the same time is able to interact with and change that context through the use of signs – read: human language and other human communicative means.

Understanding and Misunderstanding

People talk in order to communicate. Good communication happens when speakers understand each other correctly, that is, in accordance with what the speaker means and the hearer understands the speaker to mean. When such an understanding does not occur, the communicative situation becomes one of misunderstanding rather than of understanding.

Many people (including most linguists) believe that communication, and hence understanding, depends solely on the words spoken. The famous reply to a journalist's question, "Read my lips," attributed to former U.S. President George H. W. Bush, expresses a belief in the validity of the verbal utterance as proffered by a speaker, without regard either to what the speaker may have had in mind or to the actual circumstances of the speaking and reading.

Another widespread error is made by people who believe that human communication should obey

(or actually obeys) the rules embodied in what is usually called grammar (by many linguists interpreted as "a device that will generate all the correct sentences of a language, and no incorrect ones," as Noam Chomsky and his followers have preached ever since 1957, the year in which Chomsky's first and very successful treatise on syntactic structures appeared; Chomsky, 1957). This assumption (which has survived in a number of avatars, also among nonlinguists) was publicly denounced as a fallacy soon after its first public appearance; celebrated linguists such as the late Archibald Hill, anthropologists such as Dell Hymes, and sociologists such as Erwing Goffman all were quick to point out that human communication very rarely proceeds in accordance with the strict rules of grammar. Pronouncing a correct sentence belongs in the realm of the impossible, not to say pure fantasy: real people speak in ways that are rather far away from the strictures of the grammarians, yet they are often, if not always, understood correctly (in the sense in which I used this word above).

But what happens when misunderstandings occur? What are the reasons for people's wrong apprehensions of their interlocutors' utterances? Is it the case that they do not understand the words that are spoken? Or are there deeper reasons for misunderstanding?

While it is true that understanding a message to some degree depends on a correct interpretation of the words being used, as well as on a certain respect for the usual form these words and their combinations take in any given language (not to speak of a pronunciation that is not prone to being perceived wrongly, or not at all), it remains the case that words, no matter how well chosen and correctly joined and pronounced, do not convey the entire message, or even the major portion of what we intend to say. Popular handbooks of communication and advertising often propagate the slogan that in business, the words count for 5%, the body language for the remaining 95% of your message. While this may be somewhat of an exaggeration, the point these business communication experts want to make is clear: words taken by themselves will not do the job; understanding a message is more than a verbal matter.

The French philosopher Jacques Rancière (1995) distinguishes between a simple misunderstanding (French: *malentendu*, or *méconnaissance*, i.e., a wrong understanding, or even a lack of understanding) and a misunderstanding on a deeper level (French: *mésentente*), where understanding is not only difficult, but even impossible, because there is not, and cannot be, any common platform where all the involved parties can meet. According to Rancière, this is the usual, unfortunate situation especially in politics (1995: 12–13); but also in daily life, it frequently happens that one person does not understand what the other is saying, not because the words are not clear or the phrasing ambiguous, but simply because the one interlocutor does not **see** what the other is talking about, or because she or he interprets that which the other is talking about as something entirely different. In Rancière's words,

> The cases of misunderstanding are those in which the dispute on "what speaking means" [an allusion to the seminal work by the French sociologist Pierre Bourdieu, *Ce que parler veut dire*; 1982] constitutes the very rationality of the speech situation. In that situation, the interlocutors both do and do not mean the same thing by the same words. There are all sorts of reasons why a certain person X understands, and yet does not understand, another person Y: because, while he perceives clearly what the other tells him, he also does not **see** the object of which the other speaks to him; or even, because he understands, and must understand, sees and wants to make seen, another object represented by the same words, another reasoning contained in the same argument (Rancière 1995: 13; my translation and emphasis).

It is the task of pragmatics to clarify for us what it means to 'see and not to see' an object of which the 'same words' are being used, yet are understood in different, even deeply diverging ways. Notable examples of this '(mis-)use' are found in political discourse, the very subject of Rancière's reflections: words such as 'freedom,' 'democracy,' 'peace,' and so on have over the ages been consistently and willfully misunderstood and misused in political discourse. The deeper reason for such misunderstandings is not in what the words mean (and certainly not what they originally may have meant; here, the Greek roots of the word 'democracy' and its original meaning of 'people power' provide a sad example). The way we understand a word has to do with the situation in which it is being used, and that means: a situation where speakers and hearers engage in a 'common scene' (Rancière's expression) where they meet and discuss, respecting each other's background and underlying assumptions about what exactly is common to them as actors on that scene, in a particular situation of language use.

Situations and Contexts

A situation can be roughly described as a meeting of human interactants having a common background and trying to realize a common goal. Exactly how common those backgrounds and goals are can be the subject of much dispute, and even seemingly insignificant details may generate heated controversy (such as the seating order at a conference table; enter the round table, which minimizes to a certain degree

problems of seating and precedence). The situation also comprises the various real world circumstances that either have occasioned the meeting or are material in creating its context. More broadly speaking, the notion of context may be taken as comprising all the circumstances that go into defining the backgrounds and goals of the interactants, including what has been, and is being, and possibly will be, said at a meeting. More narrowly, we may concentrate on the verbal part of the meeting and the immediate environment of the words spoken, and talk of cotext, rather than context; I will use the broader term here (*see* **Context, Communicative**).

A situational context is not just a listing of what is there and who are there: it must take into account where they, the interactants, come from, in more than one sense of the term. The background from which the interactants act and speak is decisive for their possibilities of interacting (in political meetings, this is often captured by the term 'mandate'). Moreover, a context is not just given once and for all: it is a dynamic notion in that it constantly adjusts itself to the new developments in the interaction, seen against the original background (which may then be changed itself, and a new mandate given). What people bring to the situation in the guise of presuppositions and expectations is an important, albeit often not too visible part of the context. Nevertheless, and precisely because it is not directly observable, this hidden context plays a major role in determining the possibilities and liabilities of the interactants. It would be a mistake, however, to think that bringing such presuppositions out in the open automatically furthers successful interaction; in many situations, e.g., in business transactions, the interlocutors play their cards close to their chests and rely on the tacit understanding of their backgrounds that the others hopefully have, or at least pretend to have (*see* **Pragmatic Presupposition**).

Most importantly, all situations are subject to major world constraints, which govern the interactants and keep them in line, so to speak. There are both written and unwritten rules for what can be said and done and what cannot be said or done in a situation; these rules of the game depend on the way the situation is incorporated into a larger political and social frame (e.g., labor negotiations have to abide by certain rules limiting the length of the negotiating period or the extent to which existing agreements can be changed or renounced). The power that resides in the individual interlocutors (e.g., to strike a deal, to call off a strike or lockout, to conclude an accord, and so on) is vested in them on account of their social and commercial position. An interlocutor speaks not only with his or her own voice, but repeats, or re-sounds, the Voice of the Master, i.e., the institution to which he or she belongs.

This leads us to consider the speaker's role in a situation as bound by social and other convention; any speech act (see below) that is uttered during a negotiation situation can only have the force that is allowed it, based on the speaker's social and institutional placement. Conversely, such a voicing of the situation can itself contribute to the establishment of a powerful or power-like situation; words and actions interact dialectically with contexts and situations. Consider the following case, adapted from the Swiss novelist Friedrich Dürrenmatt's short story *The breakdown* (Dürrenmatt, 1956).

In the story, a traveling salesman meets three people in the dining room of a hotel in the little provincial town where he has to spend the night because his car has broken down. For some reason, the three gentlemen seem to be happy to see him, and invite him for a late supper at the home of one of their number. During and after the meal, the conversation focuses more and more on the hosts' past occupations of attorney general, judge, and trial lawyer, respectively. In the end, the trio enacts a mock court session in which the traveling salesman (who by now has lost all sense of time and space) is condemned to the severest penalties for his past misdeeds.

What is interesting here is the way in which, by force of their earlier societal standing, the three men manage to create the illusion of a court session in which the accused ends up confessing his crimes and accepting his sentence. The relevance of Dürrenmatt's legal game is that it shows us how the law is not only embodied in institutional roles and legal language, but depends on the social environment, the context in which that language is practiced. The hapless traveler who fell into the clutches of the quasi-practicing legal trio was every bit as damned as he would have been had he been condemned by a regular court.

Societally institutionalized speech acts were among the first to be discovered by Austin (1962). The concept of the social context has been valuable not only as a classificatory criterion, but also because it makes us look at what speech acts really do, and how they are able to do what they do, as we will see below. In our example, the speech act of sentencing not only brought about a changed state of affairs (the sentenced person was supposed to go to jail), but it also (re-)created the legal system whose reality it confirmed (by the pronouncing of the sentence). Not only does the social context allow for and determine what is appropriate speech acting in the context, it is itself construed through the use of the appropriate language: societal institutions are (re-)instituted through the use of speech acts. This is the social,

psychological, and above all pragmatic significance of the practical joke perpetrated on the poor traveler in the Dürrenmatt story.

Speech and Speech Acts

Above, I mentioned John L. Austin, the Oxford philosopher, as one of the great sources of inspiration for our modern thinking on how language works, or on "how to do things with words," in Austin's own immortal formulation (1962). Austin's contribution is linked to the concept of the speech act, a use of language that not only says, but does. The idea is of course not new: many of us are familiar with the institution of the religious sacrament (such as the Christian baptism). Here, the notion that a formula (such as used in administering baptism) works in force of the words spoken ("I baptize thee"), in tandem with the action performed (letting water flow across the baptizee's head). That the sacral action is performed as denoted by the words is at the basis of the belief according to which the sacrament is effective, not by force of the sayer, but by force of the words spoken and the act done. In Catholic theology, this aspect of the action goes by the label of *ex opere operato* 'in force of the act that is performed'; in speech act theory we talk about an aspect of a speech act, the performative or perlocutionary effect, that comes in addition to the words spoken (the locutionary aspect) and the point of the act (the illocutionary aspect), which makes it into precisely this act and no other (*see* **Speech Acts and Grammar**).

For Austin, speech acts could be distinguished and neatly labeled according to their 'point' or illocutionary force: ordering, asserting, requesting, and so forth. Austin's student John R. Searle, who later went back to the United States and taught at Berkeley, systematized and extended Austin's classification of speech acts and in particular, systematized the conditions that would make a speech act legal and effective (rather than 'misfiring,' as Austin called it, e.g., when the person executing an institutional act such as a marriage ceremony does not have the necessary credentials). These felicity conditions, as they often are called, comprise such matters as the agent's sincerity (e.g., in proffering a promise), the agent's or recipient's ability to be acted upon (in our society, a person cannot be legally married a second time as long as his or her first marriage is in force), and so on. Searle's merit is to have systematized not only Austin's speech acts, but in particular to have perfected his assignment of the conditions that must be met before a speech act can be said to be valid (*see* **Speech Acts**).

But there is more to this than meet the eye (or the act). Unfortunately, Searle not only developed Austin, but in doing so technologized him (Melrose, 1996: 61–62). Searle's main interest was not how to do things with words, but how to systematize and describe the words that do those things, the speech acts as such. It may be said about Austin that he never was overly technical about his speech acts – something which earned him scorn from later speech act theorists (Mey, 2001: 117–118). In Austin's original thinking, it is the words that have to be "to some extent 'explained' by the 'context' in which they have been actually spoken" (Austin, 1962: 100; the scare quotes are Austin's own). Austin is interested in the context because he wanted to "study the total speech in the total situation" (Austin, 1962: 148), which is exactly what pragmatics is all about. Whereas Austin was doing things with words, Searle is describing acts of speech.

The Problem of the Indirect Speech Act

For Austin and many of his followers, a speech act is primarily expressed by what is called a speech act verb, that is, a verb whose main function is to signal and execute the appropriate act. For instance, when I say *I promise*, the verb *to promise* is the appropriate (sometimes called canonical) expression for this particular act (*see* **Speech Acts and Grammar**).

Early on, it was noticed that many speech acts are performed successfully without the help of the canonical verb. For instance, I can confirm a promise, or even make one, by simply saying what I'm going to do, or by uttering an affirmative reply to a question. The most outstanding example of a solemn promise (a vow) that does not use the verb *to promise* is when man and wife promise each other to be faithful and supportive *until death doth them part*. The promise is uttered by the auxiliary (or tag) verb 'to do' (a tag verb is one that repeats the tagged portion of the main verb construction, as in *Do you…? Yes I do*).

More generally, the appropriate speech act can be expressed by reference to one of the conditions that Austin and Searle stipulated as necessary for successfully performing such an act. One can, for example, inquire about a person's ability to give information or perform a task, as in *Can you tell me the time?* or *Could you close that window?* In such cases, the inquiry is understood not as a mere preliminary to a request for information or action, but as the act itself of asking for information or requesting a favor, respectively. Such acts are called indirect, since they lead the addressee to infer, from the fact that a request was formulated regarding an ability or willingness,

that the request in fact was about the object of the ability or willingness (in this case, to give out information or to close a window).

Interestingly, contrary to what seemed to be the original motivation behind classifying speech acts and speech act verbs, the indirect way of doing things with words is, in many cases, the preferred one. I have called this phenomenon the 'indirect speech act paradox' (Mey, 2001; *see* **Pragmatic Acts**); it is confirmed by observations such as that by Levinson (1983) that "most usages of requests are indirect," whereas such speech as orders are seldom, if ever, executed by the canonical verb form, the imperative mood: "imperatives are rarely used to command or request" (Levinson, 1983: 264, 275; see further Mey, 2001: 111). A particular use of indirectness in speech acting is found in the phenomenon called inferring by implicature; more on this below.

Indexing and Inferring

To get a handle on the phenomenon of inference, let's first consider the use of what linguists call deictic elements. These are words and expressions that directly refer to persons, objects, situations, etc. by 'pointing' to them, using what is called *deixis* (the Greek word for 'pointing to, indicating'; the human forefinger is called 'index' because it is our first and foremost natural pointing instrument). Thus, when I say *I* about myself, I point to the person that I am; *you* points to the person away from me, *viz.*, an actual or potential interlocutor (*see* **Deixis and Anaphora: Pragmatic Approaches**).

Most languages have a more or less elaborate system of such 'pointers' that help us identify persons and situations when we are interacting verbally and otherwise. We can refer to a book that is mine, as 'this book,' whereas a book that is yours, or in your possession, may be called 'your book' or 'that book.' But deictics have other functions as well. 'That' can also express contempt (*that son of a bitch*) or respect (*gimme that old time religion*). Moreover, such 'indexing' can happen even without my knowing or willing, as when "my speech betrays me": the language I speak reveals ('indexes') my social or local roots, as happened for St. Peter in the famous betrayal scene, after he had three times publicly denied having ever set eyes on "that man," Jesus of Nazareth (Matt. 27:70–72).

Conversely, we can use this kind of indexing to provoke a reaction in our interlocutors. For instance, using high-falutin language and 'expensive' words can create an impression of scholarship and learning. When I doctor my speech to create such a (possibly false) impression, I base myself on the hopeful assumption that people who hear this particular kind of language will infer that I indeed belong to the class of educated people (alternatively, they may infer that I am a terrible snob).

As in the case of the indirect speech acts, what is said is not the whole story. Based on my actual knowledge of the world and the input from my interlocutors, I make certain inferences, albeit indirectly and perhaps not always convincingly and/or justifiably. The main point is that we are able to communicate certain thoughts or feelings, using indirect means and relying on the common world situation (or scene) that we are part of.

We imply certain things about ourselves and the world when we use deictics and other indexicals in this way; our interlocutors are supposed to make the proper inferences in order to successfully understand us or communicate with us. That such an understanding may be wrong, or even willfully distorted, is one of the secrets of the successful mystery or detective story; the innocent reader is led down a 'garden path' of false inferences, to be suddenly confronted with the real state of affairs in a moment of truth.

As an example, consider the Argentine writer Julio Cortázar's 'Story with spiders' (*Historia con migalas*; Cortázar, 1984), in which the readers are made to believe certain things about a couple vacationing on an island in the Caribbean. The sinister impact of their activities and the relationship to their earlier exploits of the same murderous kind is hinted at in the very last lines of the narrative, when the couple is unmasked as a nefarious, female duo bent on destroying men (hence the title word 'spiders,' which contains an important, but not sufficient clue). What the author does here is to play on our implicit understanding of the language (in Spanish as in English, the default couple is male plus female), in order to have us infer the normalcy of the situation, only to shock us back into the real world when the identity of the spiders is revealed, again by the use of an indexical element: a female adjectival ending. Only then do we infer the couple's identity; the rest of the gruesome inferences are left to our imagination and our ability to put two and two together on the basis of clues provided earlier. (A complete analysis of this intriguing piece of text is given in Mey, 1992) (*see* **Literary Pragmatics**.)

Next, we will discuss a particular way of implying, and see how proper inferences may be drawn using the notion of cooperation. (On inferring vs. implying, see Thomas, 1996: 58–59).

Cooperating and Implying

A pragmatic view of language bases itself, as we have seen, on the ways speakers and hearers are able to communicate in a given situation. A very important factor in this is the speakers' willingness to enter the situation with a decision to cooperate with their partners. The Berkeley philosopher H. Paul Grice is famous for having formulated the Cooperative Principle, stating the human need for, and extent of, cooperation in conversation, a principle that he detailed further in the four so-called conversational maxims, which guide the speakers and hearers through the conversational maze in a mutually satisfying way (see Mey, 2001: 71ff) (*see* **Cooperative Principle**).

The fact that cooperation is, so to speak, built into the very marrow of conversation makes us prepared to accept what is offered in conversational exchange, as being of relevance to our needs and interests. If I ask somebody for the time of day, I take it that he or she will cooperate and tell me the time, and not make some completely ludicrous remark about the state of the world. Or, "What man of you, if his son asks him for bread, will give him a stone?" as the Gospel tells us (Matt. 7:9). Conversely, we may make our intentions clear by precisely not answering a question in the expected way, or not fulfilling a reasonable request. If the father did give his son a stone for bread, he probably wanted to tell him something about the way the world is organized: people taking advantage of each other, even cheating on each other. However, in a more subtle way I can use this indirectness to appeal to an understanding of the situation that is built into the very question, so to speak. The innocent question *What time is it?* can correctly and satisfactorily be answered indirectly by referring to an event that both interlocutors know as denoting a particular time. In my Norwegian house, where we had very little traffic on the county road passing by our house, the utterance: *The bus just went by* would be a completely happy answer to a request for the correct time: there was only one bus a day, and it passed our house at exactly 7:45 AM on its way to Oslo.

When we answered the time question indirectly, we implied a reference to something that was commonly known. Grice has extended this notion of implying to something he called (with a self-concocted term, as he admits; Grice, 1981: 184–185) an *implicature* (*see* **Implicature**). Implicatures can be thought of as infringements on conversational cooperation, by going against one or the other of the conversational maxims. One such maxim is that of relation (or relevance: my answer must have some relevance to the question asked; *see* **Relevance Theory**). When we look for a relevant feature in an answer that *prima facie* seems to have little to do with what I was asking about, the implicature is of something behind the answer.

Grice's famous example is of the uncooperative college professor who, in reply to a request for a recommendation, writes that the student in question has always attended his lectures, and is a capable English speller. By not saying anything that is relevant (e.g., in a job application for an academic position), the professor implicitly indicates that the student is not a person he wants to recommend. So what at first looked like an uncooperative answer, in the end achieves the communicative needs of the situation by implicitly providing an answer that is useful to the requester.

Or consider the case of the person (related in Mey, 2001: 78–79) who is asked for an I.D. card on entering a discotheque and remarks to the doorman that she is the mother of four. Given that the drinking age at that point of time in this particular state (Louisiana) was 18, the fact of having four children more or less precludes the speaker's being under age for the purpose of drinking. But this is not said directly; the answer is a 'flout' of the maxim of relation (what does having children have to do with drinking?), but the implicature makes this a potentially good reply. In the actual case, however, the doorman refuses to recognize the implicature, and answers by another flouting of the maxim of relevance: "Yes, and I'm the Pope's granddad" – a truly absurd assertion given the ages of the then reigning pope (Paul VI in his later years) and of the doorman (at most 25). This new flout therefore implicated an answer in the spirit of: "You can tell me what you like but I cannot believe you at face value; show me an I.D. or just leave" (*see* **Maxims and Flouting**; refer also to a recent study by Greenall, 2002).

The 'Garden Path' and 'Bestrangement'

A particular form of implying is often called the already mentioned 'garden path': an interlocutor is made to infer an implicature that is not really there (but only exists in the speaker's mind), but then is intentionally suggested as valid in order to lead the conversational partner(s) astray. The motivation for creating such implicatures can be either political, as in the anecdote below (which I have called Adam in the Garden; Mey, 2001: 258–259), or of a literary kind (as in the Cortázar example referred to earlier).

During the election campaign of 1970, incumbent Congressman Adam Clayton Powell, Jr., of the 18th Congressional District, was giving a press conference outside his opponent's headquarters at 135th Street

and 7th Avenue in Harlem, New York City. A heckler interrupted him, asking him if he was going to be present at the antinarcotics parade to be held the next day, a Saturday, "like he'd promised." To which Powell replied that of course, nothing would keep him from attending. A moment later, the heckler interrupted again, wanting to make absolutely sure that the Congressman would be present at the parade. Powell, visibly irritated, reiterated his assurance, and went on with his speech. The heckler then intervened a third time, stating that "Well, Mr. Powell, sir, you ain't gonna be at that parade, 'cause there ain't gonna be one and we never spoke of one" (Source: *Harper's Magazine*, April 1971).

If we ask ourselves what was happening on that preelection Harlem Friday, we can say that the speech acts of asking questions (by the heckler) did not presuppose the existence of a real answer. The questions were disingenuous: the person asking them was well aware of their duplicity. The technique of the garden path leads the unsuspecting listener (or reader) into a verbal trap, which is then sprung at the crucial moment. Often (as in the case above), this is done with the intention of making a fool of the listener and (for political reasons, as in this case) humiliating him or her publicly. In order to better understand this technique, one could ask questions such as what speech acts can be identified in this interchange and how the Cooperative Principle applies here (if it does at all). Another interesting question would be how one could have saved Congressman Powell from going down the path, asking in particular where he took what first wrong step, and how he could have counter speech-acted to the heckler's remarks.

In other cases (mostly in a literary context) the use of the garden path is akin to the technique of making familiar things unfamiliar, a procedure called defamiliarization or bestrangement (*see* **Literary Pragmatics**). The point here is to jolt the reader and obtain some kind of narrative shock effect; the effect is obtained by allowing the reader to make the normal inferences based on what we know about society, language, and ourselves. When we enter a room, we expect there to be windows; anything that looks like a window will be seen and perceived as such. When we read about a couple taking a vacation, our inference is that of the normal, heterosexual couple. When Cortázar, in the story referred to above, suddenly breaks into our normal world by unveiling the true character of this couple, we are suddenly confronted with another view of our society, one in which the normal couple may be a same-sex one. The garden path teaches us something about the paths that are there, as well as about paths not taken by everybody.

Situated Speech and Pragmatic Acts

On the basis of the examples given, we conclude that any speech act, in order to be successfully executed, not only has to obey the conditions laid down by speech act theorists such as Searle and Grice, but in addition must be appropriately uttered, that is, it has to respect and conform with the situation in which it is executed.

A recent controversy erupting around the Danish army contingent stationed in Iraq was provoked by the fact that one of their translators balked at rendering Danish swear words verbatim into Arabic during prisoner interrogation at the Danish contingent's headquarters. Whereas the Danish interrogating officer was of the opinion that the Iraqi prisoners ought to be roughed up a bit by among other things, verbal intimidation, including threats and swear words, the native Syrian interpreter (who had spent most of his adult life in Denmark and hence was completely familiar with typical Danish swearing behavior) refused to go ahead and use words that, in his view, not only were offensive, but also would not work in the situation. He expressed as his considered opinion that an Iraqi would attribute the use of such swear terms, when translated literally into Arabic, as offensive verbal behavior, indexing an uneducated person. It would put the speaker far below the addressee, socially and interactionally, and preclude any cooperation. Hence the technique that the Danish interrogation officer wanted to employ was not appropriate to the situation, and an inappropriate act of interrogating would elicit no proper response. The interpreter, who clearly perceived the Danish and the Iraqi attitude as situationally incompatible sent in his letter of resignation 5 weeks prior to the expiration of his term, accompanied by an explanatory letter addressed to his commanding officer. This letter was then printed in the Danish press, causing a huge commotion; a public scandal erupted, resulting among other things in the Danish interrogation officer being recalled from duty in Iraq.

As we saw in the case of the indirect speech acts, such acts receive their full potential usefulness from the situation in which they are properly uttered. What is lacking in verbal explicitation, is supplied by the implicit conditions of the situation. But conversely, the situation conditions the appropriate utterances in the sense that it enables certain utterances and excludes others, as we saw in the case of the bilingual Danish-Arabic interpreter.

Generalizing these observations, we may say that no speech act is complete, or even possible, without, and outside of, its proper situational conditions. A speech act, in order to be properly executed, has to be

situated properly. This condition comprises not just the words spoken, but the presuppositions that are inherent in a situation, such as a nationally and culturally oriented understanding of proper linguistic behavior; a familiarity with conditions leading up to, as well as away from, a situated speech act; an understanding of the individual utterer's personal and social self-image; a correct interpretation of the accompanying body language and gestures; and so on and so forth. If we take all these aspects together, we arrive at the conclusion that there are no speech acts as such (except in the treatises and grammars written by linguists) and also, that every speech act, in order to be a valid act, must be rooted in a situation that supplies it with legitimacy (*see* **Pragmatic Presupposition; Intercultural Pragmatics and Communication**).

As we have seen, this legitimacy has not just to do with speaking, but more so, maybe even mostly, with the social and situational command that one has of the situation in which the words are spoken. Already Austin, in his *How to do things with words*, had had this insight (cf. the quotation above); for him, the primordial speech act was precisely a situated one. True, Austin interpreted this situation as one of strict societally defined custom (such as institutional surroundings in a court room, a lecture hall, or a church); my interpretation expands on this by saying that every situation belongs to some institution, whether officially constituted or not, and that every act of speaking is a situationally grounded and legitimated activity (*see* **Institutional Talk**). To characterize such an activity, I have coined the term 'pragmatic act' (*see* **Pragmatic Acts**). "Pragmatic acts are pragmatic because they base themselves on language as constrained by the situation, not as defined by syntactic rules or by semantic selections and conceptual restrictions. Pragmatic acts are situation-derived and situation-constrained; in the final analysis, they are determined by the broader social context in which they happen, and they realize their goals in the conditions placed upon human action by that context" (Mey, 2001: 228).

The Pragmatic Turn

From the early 20th century on, the study of language had been defined, following Saussure, as the study of its system and structure. The methods for studying language were borrowed from the natural sciences; the rules that were assumed to govern the use of language were thought of as operating on the model of physical laws, being testable according to the prediction method: a hypothesis generates a statement about certain phenomena, and we can empirically ascertain whether or not the prediction holds. So, too, a rule in linguistics should correctly predict what happens in language, and it should be as general and simple as possible, while capturing all and only the facts.

This model of linguistic methodology (accepted by all those working in the structuralist tradition, from Bloomfield to Hjelmslev to Chomsky) was subsequently refined by the incorporation of mathematical and computational methods and techniques. Chomsky's main thesis, in particular, that a grammar of a language should be able to generate all the correct sentences of a language and none of the incorrect sentences, met with wide acclaim, and became the implicit code for much of linguistic work during the latter half of the last century.

Meanwhile, as we have seen, opposition to this mechanistic way of thinking about language arose from several quarters. Not only among the linguists, but mainly among the philosophers (Austin, Searle, and their followers) and anthropologists (Hymes, Hanks), among the sociologists and conversational analysts (Goffman, Sacks, Schegloff), the insufficiency of the standard linguistic method when it came to capture the full reality of human language use was keenly felt. Also among the literary theorists, following the rediscovery of the pioneering works of Soviet thinkers such as Bakhtin, Voloshinov, and others, the interest in the social aspects of language and its use in narration in particular became a prime factor in destabilizing the current linguistic paradigm, especially as embodied in the Saussurean distinction between *langue* and *parole* (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913); Bakhtin, Mikhail Mikhailovich (1895–1975); Voloshinov, V. N. (ca. 1884/5–1936)**). In Western Europe, where the Russian scholars, for political reasons, had been rather poorly known, the surge of anti-establishment thinking of the 1960s and 1970s (spearheaded by a return to Marx) had a great impact on what we now can see and name as the pragmatic turn in language studies (*see* **Marxist Theories of Language; Social Aspects of Pragmatics; Literary Pragmatics**).

In order to properly understand the import of this turn, let's go back to the case of speech acts, referred to above. There are basically two ways of looking at human speech activity: one is to consider the language used, the other is to look at the situation in which the language is used. Clearly, the two aspects should not be separated: there is no language use except in situations, and no situation is complete without the language that goes with it. However, in a linguistics-oriented approach we will always start out with the words, then try to "fit them to the

world," as Searle used to say. The question is then: given these words, what can they do? If I say *Open the window, please*, what is the effect of this language use on the world (including the window in question, but also myself and my interlocutors, far and near)? In this approach, I start with the language and work my way to the outside, the world. The main focus in most cases is on the language used for ordering and the conditions that accompany this speech act.

Conversely, I may start out with a given situation: a window has to be closed. The question is: What language is appropriate, given the situation? I may say *Close the window, please* to somebody nearby; but I could also say, *Isn't it a bit cold in here?*, or any other indirect speech act that will do the job (sometimes even a grunt or a significant look will be sufficient). Rather than focusing uniquely on the words, pragmatics tries to capture the situation as a whole, and work its way to the inside, where the spoken words are found. Here, the use of language, such as a speech act, is an important part, but not the only one, of the situation.

In this, as in all use of language, the main protagonist is neither the language nor the situation, but the user and his or her situational conditions. The user decides on what language to use, but does this strictly in accordance with the situational context, as we saw above. Indeed, in many situations the use of a specific, canonical speech act is probably the user's last choice. One does not say *I hereby incite you to riot* to effectuate a speech act of inciting to riot – in fact, given a situation of inciting, almost any speech act will do, as Kurzon has remarked (1996). This line of thinking has led me to believe that the indirect speech act, as it is usually described, is not the exception but the normal case: all speech acts are situationally bound and conditioned, hence to a certain degree indirect in that they depend on the situation in which they are uttered.

In other words, a pragmatic approach to speech acting, and in general to language use, moves from the outside in: given this situation, what words will be appropriate for a particular act? In contrast, speech act theory, in its classical shape, works from the inside out (as does linguistics): given these words, how can I use them in a situation? This is basically the traditional semantic problem of the meaning of words; it is solved by trying to find a context in which the words will fit, rather than by starting out with the context and determining which words or expressions will fit a particular contextual slot. Curiously, it is this latter, textually based, prepragmatic approach to linguistics that was also the ideal of a structuralist like Hjelmslev: one starts from the entire text and arrives at the text's minimal constituent units through successive analytic operations; the problem was that in this kind of analysis, the user never was taken into account.

When we speak of a pragmatic turn, it is this kind of change of direction we have in mind. It is not just that some linguists turned to pragmatics, or even turned themselves into pragmaticists by fiat or "chosen affinity" (Goethe's expression). It is the method itself that has been turned on its head (or stood on its legs, if one prefers): rather than being a language-based operation, pragmatics advocates a user- and situation-based approach. It is also here that the relationship between semantics and pragmatics can be turned from an "unhappy marriage" if ever there was one (to borrow Georgia Green's expression, when she characterized the relationship between syntax and semantics; Green, 1989) into a healthy relation of mutual respect. Thus, the pragmatic turn in linguistics can be described as a shift from the paradigm of theoretical grammar (in particular, syntax) to the paradigm of the language user. The latter notion is of particular importance for defining pragmatics, since it brings a number of observations to the same practical denominator (see below; cf. Mey, 2001: 4).

It is also in this sense that we can define pragmatics as "studying the use of language in human communication as determined by the conditions of society" (Mey, 2001: 6). For, while it is true that communication in society chiefly is practiced by means of language, still, the language users, being social animals, can only use their language on society's premises. The social order controls and conditions communication in society; society controls and conditions people's access to the communicative means, in particular the linguistic ones. Given its focus on the human use of language and other communicative means, the proper task of pragmatics is to study how those societal conditions allow and determine such a use.

The Difference that Makes a Difference

A final question needs to be answered: given that we do have this pragmatic turn, and admitting that it is the right direction to take in our study of the human use of language, a question still lingers in ours minds, *viz.*: does it really mean that much which way we look at the relation between humans and their language, inside-out or outside-in? What I would like to show in this final section is that there is a difference, and that this difference indeed does "make a difference" (using Bateson's formulation).

First off, there is the emphasis that the outside-in approach places on the social aspect of all language

use. Placing the user in focus, as I advocate in the definition given above, reflects this primordial character of pragmatics as a societally based and societally conditioned study. This is not just to say that we look at social classes or groups, and then try to figure out what kind of (different) language and dialects they speak (the classical sociolinguistic approach, as practiced by, for example, William Labov and his school (*see* **Labov, William (b. 1927)**). In pragmatics, the concern is first of all to 'read' the user as a social *siglum*, a 'sign' to be decoded in accordance with societal parameters.

One of the first questions to ask then, is not what does this utterance mean? but how come this utterance could be produced at all? (Haberland and Mey, 1977, 2002) Asking the question in this way opens up an understanding of the speaker's and hearer's "affordances" (Mey, 2001: 220–221): what can a language user afford to say/hear/understand/execute as a speech act? Clearly, as already the original speech act theorists had seen, an order in the military or some other hierarchically organized body that is issued without proper authority is null and void. But even in more mundane situations (such as asking a simple question), one has always to think of what this question represents for the person who is asked to answer. Certain items may be tabooed in a particular culture; take for instance the proper name that is given a person in the Navajo community upon attaining adulthood, a name that is not to be divulged except to those with whom one has the greatest intimacy. Similarly, the old adage *De mortuis nil nisi bene* ('Say only good things about the dead') may reflect an age-old taboo: the dead may come back and take revenge when spoken about disrespectfully. The social norm, as expressed in what we now would call a superstitious belief, allows for certain types of speech and forbids the use of others, depending on the situation.

The importance of this point of view in, for instance, a teaching situation is enormous. Getting to know the background from which one's students speak is not only important in an inner city school with a majority of Black students (and often a sizable portion of White teachers), where the curriculum is geared towards White middle class values and White middle class ways of speaking and thinking are preferred (*see* **Classroom Talk**; **Class Language**). Pragmatics is also of help when trying to avoid language clashes, or even language wars, in which we construct linguistic and social differences as the barricades from which deadly battles are fought. In perhaps less serious cases, the educational future of whole generations is jeopardized because of the teachers' lack of understanding of their pupils' social and cultural background: in Botswana primary schools, students sit in the classroom and do "safe time" without learning anything useful, as Arthur (2001) has made clear; elsewhere, misunderstood language policies are imposed without regard to the students' needs (as superbly demonstrated by Canagarajah in his discussion of the language situation in Jaffna, Northern Sri Lanka; Canagarajah, 2001).

In a broader framework, one could raise the question of whether pragmatics is useful in situations like those experienced on a daily basis in the developed countries of Western Europe, where immigrants from poorer parts of the world arrived *en masse* during the 1960s and 1970s and will continue to pose problems of acculturation for many generations to come. The problems can basically be reduced to this dilemma: should people from other cultures be politely asked (or even forced) to leave their cultural baggage behind and dress up in the hosts' cultural garb, or should they be allowed (or maybe even forced) to set up their own cultural ghettoes, where they can live and breathe the familiar air of their home surroundings?

The problem hinges on a proper (that is, pragmatic) interpretation of the term 'culture' and its epiphenomenal adjective, 'intercultural.' Such a view bases itself on a pragmatic and mainly contextual understanding of culture. On the one hand, culture, in order to flourish, has to have a cultivating environment, a context; pragmatics, on the other hand, in order to be true to its definition, has to respect the individual's choice. As to the first point, no culture belongs exclusively to any individual or group of individuals; neither can culture be freely and noncontextually moved around. A culture presupposes a cultural environment, a growth context, just as the properly conditioned soil is necessary for a successful (agri)culture. But also, pragmatics as defined above is a theory of human behavior (linguistic and otherwise), which explicitly depends on, and is conditioned by, the profile of the user. Hence we must inquire as to what in the actual circumstances is culturally feasible and pragmatically desirable for the individual as well as for the group.

A great deal of flexibility is required in order to avoid either of the two extremes: the culture-only view, where one blindly focuses on a particular culture and wishes for its perpetuation, no matter what, and the pragmatic-only view, which defines the uses of language simply from a (mostly utilitarian) user point of view: what is needed to guarantee the immigrants a not only culturally, but also economically viable existence?

Through research and practice, the field of intercultural pragmatics tries to build a bridge between the two extreme positions; it safeguards the culture as culture while attending to the needs of the users.

Here, it should be borne in mind that cultures are not absolute or eternal values; even more important is the realization that humans are humans and have human needs that neither the cultural nor the pragmatic view should be allowed to abrogate. Among these needs belongs, first and foremost, the need to self-determine one's relationship to one's culture and to the culture of the host country. As pragmatic researchers, we should consequently steer a middle course between the extremes of pious romanticism and bone-hard realism, as I have indicated elsewhere (Mey, 2004) (*see* **Intercultural Pragmatics and Communication**).

Conclusion: 'Out of the Waste Basket'

From its humble beginnings as a place where one could deposit the unsolved (and perhaps unsolvable) problems that the classical parts of linguistic studies (such as syntax and semantics, perhaps even phonology) wanted to get rid of, at least temporarily, to the present state of pragmatics as a fully fledged representative of the linguistic disciplines, not much time has elapsed.

Forty odd years ago, the famed Israeli linguist Yehoshua Bar-Hillel (1971) coined the catchy phrase that figures at the head of this section; in his opinion, pragmatics served as a temporary stop for all the things that syntax and semantics could not deal with: a kind of linguistic waste basket. Now, not so many decades later, the waste basket has served its function – I am not saying it is quite empty yet, but we have managed to upgrade the basket to a more prominent position, and accorded it descriptive and explanatory status as a recognized field of language studies.

The relationship between pragmatics and the other linguistic disciplines, especially semantics and pragmatics, may still give rise to heated dispute (cf. what is said above; *see* **Pragmatics and Semantics; Phonetics and Pragmatics**), but nobody today would deny pragmatics its place in the sun. Moreover, pragmatic studies have diversified themselves into such various fields as second language education (*see* **Interlanguage**) and educational settings in general, questions of gender-based language use and language discrimination (*see* **Gender and Language**), the intercultural dilemma of assimilation vs. ghettoization (*see* **Intercultural Pragmatics and Communication**), the struggle for linguistic rights and the fight against linguistic imperialism (*see* **Linguistic Rights; Pragmatics: Linguistic Imperialism; Linguistic Decolonization; Minority Languages: Oppression; Multilingualism: Pragmatic Aspects**), and so on. Even recent developments in the area originally known under the label of human–computer interaction have begun to recognize the impact of pragmatic thinking (*see* **Cognitive Technology; Adaptability in Human-Computer Interaction**).

What this shows is first that pragmatics is not a unified discipline in the sense that it acknowledges a unique method and focuses on only one object. Second, the diversity of the areas where pragmaticists are active is best captured if we consider pragmatics not to be an independent component of linguistics (on a line with, say, semantics or syntax) but rather as a perspective on the way we study language – a perspective that at the same time informs our study of human interaction in the direction outlined above. As the British pragmaticist Norman Fairclough has observed, the pragmatic perspective being a critical one, it examines and states "the conditions under which interactions of a particular type may occur" (Fairclough, 1995: 48) – interactions that include speech acting, conversational interaction, language use in institutional settings, the discourse of literature, the prescribed language use in schools and other official surroundings, the language of sexual oppression and counter-oppression or emancipation, the fight for linguistic rights, and so on and so forth. Fairclough continues: "such a statement cannot be made without reference to the distribution and exercise [of power] in the institution and ultimately, in the social formation," that is, in society at large. (Fairclough, 1993: 48; Mey, 2001: 320–321). On the notion of perspective, see further Haberland and Mey (1977: 21), Verschueren (1999: 7), and Mey (2001: 9–11) (*see* **Power and Pragmatics; Critical Language Studies**).

The Prague linguistic circle was founded in 1926 and the Prague school, which it represented, was soon acknowledged as having systemized phonology. Its members played a crucial role in several basic branches of linguistics. A characterization of the school was presented by Vachek (1964, 1966) and by Leška (1995, 1996), see also Sgall (1997) and especially Vachek's (1960) *Dictionary,* published in English by Dušková (2003) with the inclusion of Čermák and Hajičová (2003), where relevant bibliographical data can be found. The School formulated its findings neither in a unified framework nor in a fully explicit way, but they were fruitful and still offer many substantial starting points for a systematic description of language as an essentially interactive system. Even earlier the main founder of the school, Mathesius (1911) analyzed issues of synchronic variation; having found inspiration with O. Jespersen, F. Brunot, A. Marty, and others. Ideas of the Moscow school and of the Russian formalists were brought to Prague by R. Jakobson.

The earlier prevailing Neogrammarian views, with their basically diachronic understanding of language, were changed toward what was best specified by F. de Saussure in his program of a synchronic

education and linguistic difference. Contemporary studies in linguistics and education series, Bloome D & Lemke J (eds.) vol. 1. Westport, CT: Greenwood Press. 57–75.

Prague School

E Hajičová, Charles University, Prague, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

The Prague linguistic circle was founded in 1926 and the Prague school, which it represented, was soon acknowledged as having systemized phonology. Its members played a crucial role in several basic branches of linguistics. A characterization of the school was presented by Vachek (1964, 1966) and by Leška (1995, 1996), see also Sgall (1997) and especially Vachek's (1960) *Dictionary,* published in English by Dušková (2003) with the inclusion of Čermák and Hajičová (2003), where relevant bibliographical data can be found. The School formulated its findings neither in a unified framework nor in a fully explicit way, but they were fruitful and still offer many substantial starting points for a systematic description of language as an essentially interactive system. Even earlier the main founder of the school, Mathesius (1911) analyzed issues of synchronic variation; having found inspiration with O. Jespersen, F. Brunot, A. Marty, and others. Ideas of the Moscow school and of the Russian formalists were brought to Prague by R. Jakobson.

The earlier prevailing Neogrammarian views, with their basically diachronic understanding of language, were changed toward what was best specified by F. de Saussure in his program of a synchronic

analysis of language as a system of signs (in the sense of 'sign' as a pair of 'signified' and 'signifying'), *langue,* distinguished from the use of language in discourse, *parole*. It was understood as necessary to see the collection of language phenomena as a structured whole (the structural view), i.e., as system, based on many kinds of relations or oppositions, between its units. N. Trubetzkoy's set of four types of distinctive oppositions, namely, bilateral–unilateral, proportional–isolated, privative–gradual–equipollent, and constant–neutralizable, is best known. Following de Saussure, the Prague linguists have always understood the language system in a sense similar to 'I-language,' i.e., neither as just a set of sentences, nor as a set of rules of an individual (ideal) speaker, but rather as a hierarchy of the building blocks of lexical and other complex units, with their features of different layers, which has been understood as shared by a body of speakers in general. Jakobson's general opposition of un/markedness was fundamental for the center–periphery distinction, understood as a gradual, scalar relation (see Battistella, 1995).

This structured whole, language, was understood as a functioning means of communication (the functional view). In one of the interpretations of the concept of function, functions of more or less elementary language units within complex wholes are studied, in the syntactic sense. In another understanding, 'function' is contrasted with 'means' ('tool'), and language as a whole is seen as a tool of communication. In still another sense, 'function' is opposed to 'form,' which comes close to de Saussure's binary understanding of sign. This offers a basis for understanding language as a set of levels, ordered either from meaning to expression (close to the speaker's view, stressed by Mathesius), or in the opposite direction. Thus, the levels of phonetics, phonemics, morphophonemics, morphemics, surface, and underlying syntax ('the meaning of the sentence') were established. In various discussions some of the pairs have been characterized as less fundamental than others; as for syntax, in Prague as well as elsewhere, a development from stressing surface to deposing it can be found.

Differing from the Bloomfieldian descriptive linguistics, the Praguian functionalists have also used criteria connected with oppositions intrinsic to meaning. Thus, they have been able to throw light on most different subdomains of language, from the distinction between phonetic sounds and phonemes to issues of sentence structure and linguistic meaning. Under the functional viewpoint, language was found to be of a teleonomic nature, i.e., to constitute a means–ends, or goal oriented, system as a tool serving a certain function and adapted to its requirements, i.e., to the needs of human communication. Enriching K. Bühler's approach, Jakobson (1960) distinguished six functions of language (and/or discourse), according to whether attention is primarily paid to relationships of an utterance to the context (referential function), to the speaker (emotive), to the message (poetic), to the addressee, to the communicative contact, or to the code. Jakobson's analysis of the teleonomic character of language was further discussed especially by O. Leška, M. Shapiro, F. Čermák, P. Trost, and P. Sériot. Inspired by this view, Jakobson opened new horizons in disclosing the systematic character of language development, determined by its goal-oriented nature, not just causally. The development of the intersubjective system is influenced by individual intentions of the speakers, who want to be both easily understood (avoiding too much ambiguity) and economical (reducing redundancy). Jakobson's 'therapeutic' changes restore the balance in the phonological and other subsystems, so that language can cope with the needs of communication. It remains to find means to identify the boundaries of these needs; if language behaves as a goal-oriented system, what is its regulating mechanism?

Functionalism was soon effectively applied on the two sides of the system of language concerning its minimal and maximal units, namely, handling both the nature of their sound patterns and the sentence structure in its relationships to communication. On the one hand, phonemics or phonology was created by Trubetzkoy (1939) and Jakobson as a new theory that regarded the sound patterns of languages as specific subsystems analyzed from the functional angle. The phoneme was established as the basic unit of this subsystem, the decisive criterion being that an opposition between sounds is linguistically relevant only if it serves to distinguish between semantically different words or other morphemes. In Saussurean terms, language was seen as basically consisting of a hierarchy of oppositions, and a general classification of oppositions was offered – prototypically based on markedness, binary or not, often constituting correlations, etc. On the other hand, Mathesius not only outlined a functional view of grammar (with important contributions by S. Karcevskij and others), but also devoted a concentrated effort to a structural description of the sentence understood as comprising a patterning primarily conditioned by the interactively based role the sentence plays in the context in discourse; thus, he integrated the topic–focus articulation (TFA, information structure) into the structural analysis of the sentence.

Also issues of poetic style and of the semiotics of arts were studied in close connection with the teleonomic view of language. R. Jakobson, J. Mukařovský,

and R. Wellek presented many-sided analyses of the interface between linguistics and aesthetics. These aspects of the Prague school theories, which have been of substantial impact on the theory of literature and on the semiotics of arts in many countries, cannot be pursued in detail in the present article. The relationships between linguistics and aesthetics are much looser today, although in certain domains the interface still is the object of revealing interdisciplinary studies, such as M. Červenka's analysis of functional sentence perspective (TFA) in poetry and fiction.

The approach to language as a means of human communication led to analyzing pragmatic aspects of the use of language and its varieties. Issues of stylistics, the functions and properties of standard language, 'functional languages' (comparable to what more recently has been called 'sublanguages'), other varieties of national language, and (individuating) styles were analyzed especially by B. Havránek, whose studies have been important for what preceded modern sociolinguistics and text linguistics. The intrinsic closeness of stylistics and the functional stratification of language is clearly to be seen in the complex situation of Czech, with its rich and controversial variety of the speakers' attitudes toward non-standard items in everyday speech (recently discussed by P. Sgall, F. Čermák, L. Bayer-Nerlich, and others).

Starting with the 1940s, both a considerable geographic expansion of the Prague school views and an extension of its research to most different subdomains of linguistics was achieved, although during the Nazi occupation the activities of the Prague linguistic circle were substantially restricted. R. Jakobson, who had to emigrate, found a possibility to deepen the principles of the school, applying them to fundamental issues of language structure (in part together with M. Halle), and initiating a large-scale deployment of research based on Praguian principles in the United States in the domains of Slavistics, general phonemics, and semiotics, concentrated around the journal *Word* and including the personalities of C. H. van Schooneveld, A. Martinet, L. Matějka, M. Shapiro, D. Worth, E. Stankiewicz, and many others. Also in Europe the impact of the school continued to be felt. Although scientific and personal contacts between the different parts of the continent were difficult, linguists such as J. Kuryłowicz, A. A. Reformatskij, R. I. Avanesov, P. S. Kuznecov, E. M. Uhlenbeck, M. A. K. Halliday, K. Heger, Y. Tobin, and others in different countries contributed substantially to the school's work and impact. Holenstein (1975) presented a deepened analysis of Jakobson's work. Schools of functionalist linguistics that came into existence in different parts of the world, as well as approaches of several Slovak and Czech linguists working abroad, such as A. V. Isačenko, Ľ. Ďurovič, J. Neustupný, and J. Toman, differ from each other, but nevertheless reflect Praguian views and methods to a higher or lower degree, and have substantially enriched Praguian traditions, which have found regular and broad reception in most Slavonic countries.

The development of the school in Czechia can be followed first of all thanks to various contributions and collections of articles published in the West; see Vachek (1983), Luelsdorff (1994), and Luelsdorff *et al.* (1994). The activities of the Prague linguistic circle, reassumed in 1945, were stopped at the beginning of the 1950s, but in fact, the tradition did not get lost, although the name of the circle was mentioned only rarely in Czech publications. The series of *Travaux du cercle linguistique de Prague* was virtually revived in the 1960s (thanks to J. Vachek and F. Daneš) in the shape of the *Travaux linguistiques de Prague,* which was stopped with its fourth volume after the Soviet-led invasion. In 1989 O. Leška initiated the revival of the circle, and the publication of its *Travaux;* four volumes have been published already by J. Benjamins (Amsterdam and Philadelphia, with a parallel English title: *Prague linguistic circle papers*).

A structuralist approach to the typology of language was elaborated by V. Skalička, who – inspired by the teleonomic approach, Jakobson's implicational laws, and V. Mathesius's 'characterology of languages,' – worked with probabilistic relations. As P. Sgall pointed out, a single predominant feature of each of the types can be specified, from which the probable presence of other features can be deduced and which concerns the way of expression of grammatical and derivative values (by free or bound morphemes, by alternations, and by the order of the lexical items).

The understanding of the levels of the language system was deepened especially by B. Trnka and O. Leška. Trnka's writings, which already earlier started the phonological analysis of English and contributed to a characterization of the role of structural linguistics in the thought pattern of the first half of the 20th century, were continued by J. Vachek, whose work has been equally significant for an explanation of the role of written language. I. Poldauf's inquiry into syntax (postulating a level of evaluational expression of the speaker's attitudes) and L. Dušková's analysis of the verb system confirm how fruitful a comparison of Czech and English has always been for Czech linguistics. A systematic approach to word formation (derivology) was formulated by M. Dokulil, and the morphophonemics of Czech

found a profound analysis in the writings by M. Komárek.

Most important for the fundamentals of structural syntax have been the writings of a French member of the circle, L. Tesnière, representing the first systematic elaboration of dependency (valency-based) syntax. E. Pauliny understood the valency ('intention') of the verb as being primarily linked with functions of cases. Inspired by the Saussurean opposition between linguistic (literal) meaning and cognitive content, also discussed by L. Hjelmslev, E. Coseriu, and others (not without connection with Jakobson's view of meaning invariants), M. Dokulil and F. Daneš characterized the level of 'sentence meaning' (one of the first versions of underlying syntax) as a linguistic patterning of the layer of ontological content, i.e., in recent terms, a level of interface between the system of language and the semantico–pragmatic interpretation, helping to distinguish the language system from both its underlying cognitive categorization and its semantic interpretation. The present-day theory of valency (P. Sgall, J. Panevová) is being extended from the domain of verbs to nouns and other word classes and includes a distinction between two oppositions: along with the classification of the types of dependency themselves (valency frames or grids, i.e., inner participants and 'free' circumstantials, or arguments and adjuncts), another opposition concerns the relationships between a valency grid and the (larger or smaller classes of the) head words; prototypically, but not always, an argument is obligatory, and an adjunct is optional (peripheral cases are, e.g., obligatory adjuncts, such as with *to behave somehow, to arrive somewhere*). Syntax has been studied as reflecting the impact of factors originating in everyday speech esp. by M. Grepl and P. Karlík in Brno.

The division of the sentence into topic and focus (theme and comment or rheme), based on the cognitive opposition between 'given' and 'new' information, was analyzed by Firbas (see 1992), who introduced the opposition of contextually bound and nonbound items and 'communicative dynamism' as a scale proceeding from theme proper (typically at the beginning of the sentence) to rheme proper (marked by the sentence stress), as well as by F. Daneš, A. Svoboda, and others. Attention has been paid to the issues of negation and presupposition, to which E. Hajičová added the concept of allegationas a specific type of entailment. It has been demonstrated the dichotomy is relevant for the truth conditions of the sentence (cf. e.g., *She writes her dissertation on SATURDAYS* vs. *On Saturdays, she writes her DISSERTATION.*); thus, the dichotomy is an inherent part not only of an interpretation of an utterance (sentence occurrence in a discourse), but also of the underlyingsentence structure. F. Daneš pointed out how the 'thematic progressions' relate the theme–rheme dichotomy of an utterance to its position in a discourse (the theme often being coreferential either with the rheme or with the theme of the preceding utterance). Daneš and his collaborators have contributed many-sided analyses of relationships between sentence structure and various aspects of discourse patterns.

A new support for lexical as well as grammatical inquiries has been offered by the recent progress in corpus linguistics, achieved by the build up of the Czech National Corpus, which allows for providing online information on most different properties of individual word forms, lexical items, and other units in written Czech. A complex system of semiautomatic grammatical annotation of texts from the corpus has been prepared as a basis for the Prague dependency treebank, designed by J. Hajič and others. The treebank includes a morphemic tagging, the 'analytical' or 'surface' representations (having the shape of dependency trees, the nodes of which correspond to all word occurrences, including function words and punctuation marks), and the underlying tectogrammatical representations (TRs) in the sense of FGD (see below). A difficult work aiming at a corpus of spoken Czech has started already in Prague as well as at Masaryk University in Brno.

Discussions about the arbitrary character of the linguistic signs have led to a modified form of the Saussurean tenet, taking into account a limited intralinguistic motivation. This view, reflected already in V. Mathesius's distinction of descriptive (motivated) vs. simple nomination, has been further elaborated primarily in the domain of idioms. The difference between Praguian approaches and the framework of sign-based linguistic theory as known from the Schooneveldian trends might not be that large as is sometimes believed.

One of the major controversies in the past was whether de Saussure's distinction of synchrony–diachrony is satisfactorily established. Jakobson and Trnka especially raised numerous objections against this distinction, not linking this opposition with the crucial notion of the state of language, which in each of the historical periods must have its own system.

The discussions briefly characterized above offered an appropriate basis for a fully explicit, formal, and electronically implementable formulation of the framework of language description, which, initiated by P. Sgall in the 1960s, was elaborated by the research group of theoretical and computational linguistics at Charles University, Prague (E. Hajičová, J. Panevová, P. Pit'ha, Z. Kirschner, J. Hajič, A. Bémová, E. Buráňová, and others) as functional

generative description (FGD; see Sgall *et al.,* 1986; Hajičová, 1993; Sgall, 1993); the empirical adequacy of FGD is being checked with the help of the work on PDT. FGD uses a dependency based syntax with which the underlying, tectogrammatical representations (TRs) of the sentence core have the form of dependency trees. The complex labels of the nodes of these trees indicate (a) lexical meanings, and (b) values of grammatemes, i.e., morphological categories such as tense, aspect, number, etc. The labels of edges indicate the valency slots or kinds of the dependency relation, i.e., arguments (actor, addressee, objective, origin and effect in Czech as well as in English, French, German, Russian, and other languages) and adjuncts (means, locative, manner, different directions and temporal modifications, conditions, cause, aim, comparison, etc.). Other kinds of syntactic relations are those of coordination (conjunction, disjunction, and others) and apposition. Their interplay with dependency cannot be accounted for by trees, for more than two dimensions are needed. However, the relationships of the different dimensions are strongly restricted by such conditions as that of projectivity (adjacency) and similar restrictions holding for the relationships between coordination and the two basic dimensions of the tree. Thanks to these restrictions (not relevant for the morphemic representation, which has the form of a string of morphemes and their parts), the representations can be handled by limited means; they can be denoted by a linearized version of the TRs, namely by a parenthesized string of complex symbols, which is not substantially more complex than the formulas of the proposition calculus. Thus, the core of the sentence can be understood as patterned in a way that does not substantially surpass general human mental abilities. This may help understand why the child's acquisition of language is relatively easy, being supported more by the interactivity of language use than by a complex innate mechanism.

The TRs include a specification of the topic–focus articulation, expressed mainly by an interplay of word order and sentence prosody (especially the position of the intonation center); in the TRs it is represented by the left-to-right order of the nodes, with the topic standing to the left of the focus. The systemic ordering of the complementations underlies their canonical order, which determines the degrees of communicative dynamism within the focus. Thus, if A precedes B under the systemic ordering, B can only be less dynamic than A in a sentence, if B is contextually bound, i.e., primarily belongs to the topic: compare, e.g., *We came from a small village to an industrial town* (where the *from* group belongs to the focus on one reading and to the topic on another) vs. *We came to an industrial town from a small village* (where the to group belongs to the topic on all readings). The prototypical position of such specific items as negation and particles such as *only, even, also* is such that they semantically operate on the focus. On the basis of a principled discussion, these issues have been investigated by Hajičová *et al.* (1998), together with an analysis of the relevant aspects of the semantico–pragmatic interpretation of the sentence using the framework of formal (intentional) semantics.

Prague linguists always have paid attention to issues of discourse. An utterance, i.e., an occurrence of a sentence in a discourse, has been understood as an act of *la parole* that is identified by the unity of the speaker, time, and place and may be interpreted as an elementary semiotic reaction to an impulse of some sort; its study represents the first major breakthrough into the territory of the process of communication. The theoretical approach to discourse has been connected in Prague with several other aspects of the functional structuralism, from the attention paid here to stylistics down to the teleonomic views mentioned above. Relationships between sentence structure and discourse have been discussed by Sgall, who points out that underlying representations (TRs) may only serve as a starting point for semantico–pragmatic interpretation if the reference of the individual referring items is specified, on the basis of which a proposition as a function from possible worlds to truth values is determined. The way toward discourse semantics can then be traced, especially if the notion of discourse referent is enriched in what concerns the contextual boundness of the given item. Another enrichment concerns the basis for the choice of antecedents in cases of coreference, consisting of the hierarchy of salience of the elements of the set of referents that are understood by the speaker to be easily accessible to the addressee in the given time point of the discourse. This set, called the stock of shared knowledge, displays dynamic properties, certain aspects of which have been studied by Hajičová *et al.* (1998) Further contributions devoted to the nature of communication and to different aspects and kinds of discourse, from everyday dialogue to the language of advertising, have been recently presented by F. Daneš, J. Kořenský, S. Čmejrková, J. Hoffmannová, and others.

It may be claimed that all of the notions referred to above, representing an organic and compact blend of both prewar and postwar thinking, have become international and are also being used, in varying degrees, in non-Prague milieus. Their impact may be different in different countries, but all of them seem to have remained stimuli for others.

Language plays a major role in prayer and meditation in all the world's religious traditions. However, there are enormous differences in what might be understood by the terms language, prayer, and meditation in different religious traditions. This article explores aspects of these understandings in a variety of religious traditions.

The earliest forms of prayer and meditation which we can investigate are those of the religious traditions of hunter-gatherer peoples whose cultures survived into modern times. Studies of cultures such as those of the Amazonian Indians have shown that activities akin to prayer and meditation form an integral part of these traditions. Indeed, it is also clear that language plays an important role in these activities, both in terms of spoken supplications to spirits and in terms of descriptions of states of spirit possession which are a feature of the religious traditions of hunter-gatherer peoples.

It is also apparent that in these religious experiences there is reversal of what might be seen as the normal role of language, to be a system of symbols by which communication about the nature of the world we live in is carried out. Instead language becomes an act through which the world is created. It could be argued indeed that this is a distinctive feature of language in prayer and meditation, language takes on the role of that which summons up the world and creates the reality in which the religious practitioner exists.

This idea of the word actually creating the world is at the heart of the Judeo-Christian tradition where it is the word of God which sets in motion the creation of the world itself. The power of the act of speech is also integral to earlier Middle Eastern religious traditions. Thus in Egyptian and Babylonian traditions, prayer forms a major part of religious activity. Indeed, the earliest written prayers may well be those from Egyptian tombs where, during the fifth dynasty in around 2400 B.C., written lists of offerings to the gods developed into written versions of prayers to the gods asking for their blessings for those who were beginning the journey into the afterlife.

Prayer and Meditation

P G Friedlander, La Trobe University, Melbourne, Australia

© 2006 Elsevier Ltd. All rights reserved.

Language plays a major role in prayer and meditation in all the world's religious traditions. However, there are enormous differences in what might be understood by the terms language, prayer, and meditation in different religious traditions. This article explores aspects of these understandings in a variety of religious traditions.

The earliest forms of prayer and meditation which we can investigate are those of the religious traditions of hunter-gatherer peoples whose cultures survived into modern times. Studies of cultures such as those of the Amazonian Indians have shown that activities akin to prayer and meditation form an integral part of these traditions. Indeed, it is also clear that language plays an important role in these activities, both in terms of spoken supplications to spirits and in terms of descriptions of states of spirit possession which are a feature of the religious traditions of hunter-gatherer peoples.

It is also apparent that in these religious experiences there is reversal of what might be seen as the normal role of language, to be a system of symbols by which communication about the nature of the world we live in is carried out. Instead language becomes an act through which the world is created. It could be argued indeed that this is a distinctive feature of language in prayer and meditation, language takes on the role of that which summons up the world and creates the reality in which the religious practitioner exists.

This idea of the word actually creating the world is at the heart of the Judeo-Christian tradition where it is the word of God which sets in motion the creation of the world itself. The power of the act of speech is also integral to earlier Middle Eastern religious traditions. Thus in Egyptian and Babylonian traditions, prayer forms a major part of religious activity. Indeed, the earliest written prayers may well be those from Egyptian tombs where, during the fifth dynasty in around 2400 B.C., written lists of offerings to the gods developed into written versions of prayers to the gods asking for their blessings for those who were beginning the journey into the afterlife.

In a sense it is quite possible to see a development from the invocations of spirits in the religious traditions of hunter-gatherer peoples through to the notion of prayer as a form of address to a monotheistic deity in the Judeo-Christian tradition.

The development of meditation in Judeo-Christian tradition is often linked to the Essene traditions, which were desert-dwelling ascetic traditions of the Middle East. The role of language in the early contemplative practices of Christianity can be glimpsed through texts such as the Nag Hamadi texts, or the Dead Sea scrolls, as they are sometimes called. In these it is evident that contemplation of the names of God was an element in meditation practices. In the Jewish Kabbalah there is also a strong tradition of meditation on the letters of the alphabet, and on manipulating the letters of the alphabet into mantra-like focuses of concentration in meditation.

It is also perhaps in relation to these Middle Eastern traditions that one of the origins of the notion of the inherent sacredness of the written word can be glimpsed. In the context of the meditative communities dwelling in the deserts, the act of writing sacred scripture became part of the meditative life itself, and this tradition was carried on into the Middle Ages and led to the production of glorious illuminated manuscripts such as the book of Kells.

Another development of the Middle Eastern tradition of reverence for the written form of sacred texts is strongly manifest in the Islamic tradition where, due to a prohibition on the representation of human forms in sacred spaces, a tradition of calligraphy developed. Middle Eastern traditions also incorporate singing traditions, such as Judeo-Christian hymns and chants and Islamic chanting of sacred texts as performed by Muezzins when calling the faithful to pray and by Sufis when they are practicing rituals to develop altered states of consciousness.

Prayer in its origins also has much to do with sacrificial ritual and invocations within rituals. In this context it is evident that the correct form of a prayer becomes a matter of major concern, for like a spell, if spoken incorrectly, it might not have any effect, or worse still, might summon up the wrong spirit altogether.

In South Asian tradition Vedic rituals were, and are, a cornerstone of religious culture. Prayer, in the sense of the invocation of the gods, forms a vital aspect of Vedic sacrificial rituals. It was also considered that the rituals would only be effective if the prayers were recited correctly. This was vital, because in South Asian religious traditions the performance of the ritual was seen as bringing the worlds of the gods and men into alignment. If there were no sacrificial rituals performed, or they were performed incorrectly, the world, and its inhabitants, would not be looked on beneficially by the gods.

Vedic traditions were initially nonwritten, so in order to ensure that the texts were remembered correctly, elaborate training in chanting the texts was practiced. For instance, there are normally said to be four Vedas, sacred texts, and one of them is basically concerned simply with how to correctly remember and recite the other three Vedas.

To the extent we could separate out a category of prayer in Indian tradition we might also identify it with the tradition of *stotra,* verses recited in praise of particular deities. These often also include enumerations of the names of the manifold forms of particular deities in works such as the 'Thousand Names of Visnu' (*vishnusahasranama*). However, it could be argued that a feature of Indian tradition is that such works are both prayers, entreaties addressed to deities, and also meditations on deities. Indeed, the notion that we might seek to separate out prayer and meditation into two mutually distinctive categories does not spring naturally from the terms and ideas practised in South Asia.

India is also famous as one of the cultures in which meditation traditions developed. There are references in the Vedas to what appear to be meditative practices and clear accounts of meditation in the Upanishads. That language is an important aspect of meditation is also stressed, and there are descriptions of meditation upon the names of gods and of meditation on the sacred sound 'om' as being a key element in some meditation practices. 'Om' is often envisaged in India as the primal sound from which all of creation is manifest.

In the medieval period in India during the growth of the devotional cults based around loving devotion, or *bhakti,* the name of god also assumed great significance. For those who followed the path of devotion to a formless deity it became synonymous with the deity in its self. There are numerous stories that emphasize that even the utterance of part of the name of god is sufficient to form an entreaty to them for aid. For instance there is a story in the *Bhagavata Purana* about an elephant who was being attacked by a crocodile and uttered the sound 'ra' in a roar of pain, and as this is the first syllable of the name Ram it was sufficient to attract the attention of Ram who rescued the elephant from his predicament. Such stories are normally told in the context of praising the virtue of chanting the names of god. The practice of chanting the names of deities such as Krishna and Ram acts both to foster in the devotee the virtues and qualities of the deity and also to attract their attention so that they may look sympathetically on the devotee. Chanting the names of god is at once a form of prayer, a supplication to the deity, and a form of meditation.

It should be mentioned that a particular form of chanting practiced in some forms of Hindu devotional tradition is what is called the chanting of the unchanted chant, the *ajapa jap*. The practice of chanting the unchanted chant is said to lead to the cognition of the 'unstruck sound' the *anhad nad,* which is a sound which is not a sound, but rather the fundamental sound of the universe audible only to the practitioner in deep meditation.

The chanting of the names of god is also a feature of Buddhist practice. Buddhism developed in South Asia and shares in various characteristics of its practices, which are often identified with Hinduism. However, there are normally important ways in which Buddhist tradition attributes new values and significance to its practices. A common ground of ritual activity in South Asia is the practice of *puja,* the adoration of a particular deity which is invited to enter into some form of physical manifestation, such as an image, and is then worshipped by various means such as offerings of lights, incense, food, drink, and words of praise and supplication. Language is an intrinsic feature of such rituals, as without invocations and resolutions the ritual cannot begin, and without utterances honoring the spirit or deity invited, or the Buddha, it cannot be brought to completion.

Buddhist meditation traditions take various forms, in some of which language has a greater focus than in others. In insight meditation (*vipassana*) practitioners seek to identify the ways in which all phenomena are by nature without self essence, impermanent, and unsatisfactory. In such practices language is used in order to break down the elements of experience into basic phenomena, but in itself is not a subject of meditation. Likewise in calming meditations (*samatha*) practices, language is used as a tool for meditation, but is not itself an object of meditation.

It is more fruitful to look rather at Buddhist meditation practices that involve meditations on mantras of particular forms of the Buddha. These are typically found in Tantric traditions, as practiced in Tibet in the modern world. In these there is a conscious use of language as part of meditation and ritual. However, it is important to note here that, in this context, it is explicit that language must refer not only to spoken utterances, but also to bodily actions and to visual representations. A Tantra in this sense involves all the senses; it is at once a ritual, a symbolic diagram (often called a Mandala in English today), a set of texts to chant, and an oral tradition of interpretation of those texts handed down from master to disciple.

I mentioned earlier that, in an apparent inversion of the normal worldly function of language as a way of understanding the world, in prayer and meditation language becomes a way to create the world. This is perfectly epitomized in Tantric practices, in which the first stage of a Tantra is the generation of a world, a realm in which the actors play their parts, the practitioners inviting the various deities to manifest their presence. However, it is then followed by a dissolution stage, in which the world created by the ritual, through the language of sound, symbol, and action, is dissolved into the ultimate state of nothingness from which all things emerge. Finally, at the end of the ritual, the practitioners once more emerge into the conventional world in which they began the ritual.

Language is thus an integral part of prayer and meditation in the religious traditions of the world, and it is notable that it plays a key role in the way that it acts as a way in which the religious practitioner is able to summon up spirits and, in a sense, create the world itself.

Preaching

R Allen, Christian Theological Seminary, Indianapolis, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Although the term 'preaching' is often associated with religions descended from Sarah and Abraham, similar phenomena (sometimes with differing names and nuances) occur in many other religious movements. The following is a broadly based functional definition (Osborn, 1976: 53–54):

> Preaching is a human activity characterized by specific marks: (1) It is a sustained mode of public address, (2) dealing with a religious or ethical theme, (3) bearing witness to the faith of a community, (4) rooted in a holy tradition (a tradition defined in a sacred 'literature'), (5) occurring within an assumptive world of rationalized belief, (6) communicated through the person of the speaker, (7) employing the forms of verbal art, (8) possessing the character of immediacy, (9) intended to convert the listener, (10) conveying powers of renewal to those who hear.

To be sure, not all elements of this definition are present in every understanding of preaching. For instance, some groups regard preaching as intended less for conversion and more for teaching and nurture. Within particular religions, different groups understand preaching in different ways.

Functions and Forms of Preaching in a Sampling of Religions

In most Christian congregations, the sermon is given by a minister, priest, or other person designated by the congregation or the Holy Spirit. The content of the sermon is typically an exposition of a biblical text or Christian doctrine or a theological interpretation of a personal or social situation designed to help the congregation discern God's leading and to respond accordingly. In some churches, the sermon at the regular time of worship is designed for both nurture and conversion, whereas in many congregations the sermon is aimed primarily at building up the congregation, with evangelism (offering opportunities for conversion) taking place in other services and at other occasions.

In Judaism, as part of the synagogue service, the rabbi typically gives the sermon. The function of the Jewish sermon is indicated by the title 'rabbi,' which in Hebrew means 'teacher,' whose calling is to reinforce the identity of the community and to help the community determine how to live and witness faithfully. The rabbi often takes a text from the Bible (or the Talmud or some other significant source of religious insight) and explains the meaning of the text and its implications for today. Rabbis sometimes develop topical sermons on significant personal or cultural issues; that is, instead of focusing on a particular sacred text, the sermon focuses on the theological interpretation of a social, political, or personal issue.

In Islam, a primary responsibility of the imam (leader and teacher of the mosque) is to lead the worship of the community, called the *salat*. The imam not only calls out the ritual words but also models the physical postures that are a necessary part of the worship. The congregation follows the lead of the imam. Portions of the Qur'ān are read. The mosque typically contains a pulpit for the sermons that are given on Friday either at noon or at sunset. The Friday worship includes a preacher (*khaṭīb*), normally the imam, who gives a sermon (*khuṭbah*) that is relatively short and that explains aspects of Muslim doctrine, exhorts the congregation to faithfulness, and warns against departing from aspects of Muslim devotion and life. Preachers sometimes comment on social and political matters from the perspective of the convictions of Islam.

Indigenous religious life in Africa varies greatly from area to area and from group to group. However, many different African peoples, especially in West Africa, contain a figure often called the *griot*, who performs a function similar to preaching in the three religions previously discussed. The griot tells the stories that tell the community of the origins of the world, the emergence of the community and its genealogy, along with the purpose of the community and how to live so as to fulfill that purpose. The griot sometimes uses musical forms in narrating the community's story.

The religious lives of Buddhists, Hindus, and Confucians do not presuppose the importance of weekly congregational gatherings with a sermon that are constitutive of Christianity, Judaism, and Islam. Worship in the former religions tends to take place in smaller groups (e.g., with other members of one's household) of even individually. However, each group has moments of encounter when guidance or exhortation takes place that is similar in function to that of preaching. As the following discussion makes clear, worship within these groups can be quite diverse.

Soon after Enlightenment, the Buddha gave a discourse on meditation and Enlightenment that is sometimes referred to as a sermon. However, the heart of Buddhist worship is personal meditation that sometimes takes place at a temple. Some Buddhist groups in North America do gather for worship that

occasionally includes a sermon (usually instruction in meditation). Buddhism contains enlightened teachers whose instruction is usually given to individuals or small groups but that functions for Buddhists much like the sermon in Christianity, Judaism, and Islam. Buddhism also honors a holy person whose spiritual experience is so deep that it cannot be described in words. Indeed, the riddles of the Zen masters testify to a knowledge that is beyond communication.

Hinduism teaches that God is within every entity in the cosmos as well as transcending the cosmos. Each soul is divine. A goal of worship in Hinduism is for people not only to become aware of that divine essence but also ultimately to experience it directly. Although Hindus have temples where worship takes the form of prayer and meditative rituals, individuals engage in such actions at their own pace. Even in North America, where occasional Hindu groups do meet at specified times for worship with a more communal character, there is seldom a sermon. However, in Hinduism the guru in settings outside worship performs the function of the sermon by educating the people in the basic principles of Hinduism and in how to apply them to life. Hinduism, like Buddhism, honors the holy person who does not give instruction, but who lives a spiritual existence unaffected by the cosmos, due to community with the divine in modes that go beyond words.

Although Confucius intended not to found a religion but to teach morality and social doctrine, a religious movement grew up after him. At the heart of Confucius's teaching is the belief that the deepest moral values of the universe can be manifest in everyday courtesy and respect. Although the Confucian sage does not continue this tradition of instruction in communal worship, the sage does carry out one of the key functions of such preaching in other settings by showing how universal truth applies to current life.

Preaching in Historic Christian Movements

Preaching functions in slightly different ways in historic Christian movements. Within each of these movements, the preaching is often adapted to the particular culture of the local community. For instance, preaching in African American churches related to the historic Wesleyan movement often incorporates qualities associated with African religions. Preaching in a Reformed Hispanic congregation often manifests qualities of Hispanic life.

In the Orthodox churches, the sermon is not simply an interpretation of doctrine or the Bible but functions much like an oral–aural icon. An icon is a medium through which the congregation experiences the heavenly world. At its optimum, listening to the sermon is a means of participating in the theological reality bespoken in the sermon.

The Second Vatican Council (1963–1965) gave Roman Catholic preaching its current shape by identifying four emphases for the sermon: (1) The sermon is to be biblically based and (2) work together with the Christian year and the lectionary and other parts of the service while (3) announcing God's good news for the world (and not simply imparting moral guidance) in (4) language and style that is familiar to the people. Preachers can employ a variety of sermonic styles and can refer to their personal experience.

Like its counterpart in the Roman Catholic tradition, the sermon in the Anglican communion derives from a passage in the Bible, is integrated into its liturgical setting, is (usually) eucharistic, is kerygmatic, and is in the language of the social context. A lectionary provides the Bible content and the preacher's calling is to help the community interpret how the passage connects with motifs from the Christian year and Christian doctrine. These churches believe that the Holy Spirit manifests the Real Presence of Christ through the homily.

Lutheran sermons also focus on texts from the Bible offered by a lectionary and in the setting of the Christian year. Many Lutheran sermons begin with law, with its double indication of sin and the inability of humans to save themselves, and move to gospel, with its news of justifying grace. Lutheran preaching often also guides the community in responding to grace. Some Lutherans regard the pulpit as a combat zone between God and the devil.

The Reformed sermon is a teaching event. The preacher often indicates how God's grace is assumed in a biblical text, names ways that grace continues to work, and guides the congregation in response. Calvin spoke of a third use of the law as providing direction for life. From the Reformation into the late 20th century, much Reformed preaching was based on *lectio continua* – that is, preaching sequentially through books of the Bible.

At the time of John Wesley, sermons had become quite ornate. Wesley believed such preaching obscured the plain truth of the gospel and sought simple and direct sermons that gave the Holy Spirit optimum opportunity to work in the believer and the community. Wesleyans seek for the community to become cognizant of its need for God and of Christ as God's compassionate response. The sermon points the community toward living the sanctified life.

For Anabaptists, the sermon is typically the focal point of the hour of worship. Starting from a biblical text or theme, the preacher seeks to convict the

congregation of its sin and to awaken the desire to repent. More important, the sermon points the community to God's grace in Jesus Christ. In many Baptist congregations, the sermon concludes with an invitation to the unconverted who are present to make a confession of faith and to be immersed. The churches that began in the radical reformation add emphasis on the community keeping itself distinct from the world to maintain the distinctiveness of its witness to the world. The sermon, then, includes ways of helping the people maintain their distinctive life and witness in the large social setting.

Silence plays a major role in the worship of the Society of Friends as they wait for the Spirit to move some in the community to speak. Many Friends believe that the risen Jesus directly speaks to the community through the silence and through worshippers who are moved to speak. The risen Jesus continues directly to teach the contemporary community by means of the Spirit speaking through members. Some meetings (as congregations are called) are unprogrammed – that is, they take place in almost complete silence. Others are programmed – that is, they are more like services of worship in other Christian denominations and include a sermon as well as a significant period of silence. The sermon can be an occasion for the risen Jesus to teach the congregation.

Pentecostal worship is centered in the immediate experience of the Spirit, who fills believers and preachers with ecstasy that is often evident in speaking in tongues. Such churches believe that the Spirit moves through the preacher and the sermon. Indeed, some Pentecostal pastors so rely on the inspiration of the Spirit that they make little or no preparation for the sermon. Most Pentecostal ministers believe that the Spirit can anoint the process of sermon preparation. However, they also remain open to the spontaneous leading of the Spirit at the moment of preaching. Pentecostal preaching calls particular attention to the presence of the Spirit in the Bible and in the immediate life of the congregation and provides guidance for the congregation to respond.

Although of recent origin and existing mainly as independent congregations, Bible churches and community churches (and congregations that are known similarly) long for forms of worship and Christian life that are in harmony with simple biblical Christianity. Centered in a divinely inspired Bible, the preacher is set aside by the congregation to explain the theological meaning of the Bible and to name its implications for the present.

Within several of these historic families, there are four different contemporary theological emphases that lead to different qualities in preaching. Some preachers are evangelical or fundamentalist in theology. Believing that the Bible is divinely inspired, they see the work of the sermon as clarifying the Bible and applying its truths directly to today's world. Postliberal theology seeks to narrate today's congregation into the world of the Bible. The preacher interprets the world of today from the perspective of the biblical text. Revisionary theology explores mutual critical correlation between the Bible and the world. The revisionary preacher asks how contemporary perspectives on the world prompt the community to revise its understanding of the Bible and how the Bible urges the community to revise its understanding of the world. Liberation theology sees God's primary work as that of liberating individuals and communities from multiple (and often interlocking) forms of oppression. The liberation preacher names repressive powers, shows how God is acting to free people from them, and suggests how people can take liberating actions.

Predication

S Rothstein, Bar-Ilan University, Ramat Gan, Israel

© 2006 Elsevier Ltd. All rights reserved.

The predication relation was introduced into discourse about language by Aristotle in 'On Interpretation,' (paragraphs 5 and 6) when he defined a proposition as an instance of predication, which "asserts or denies something of something." He thus introduced into philosophical and linguistic discussion two central ideas: (a) the syntactic idea that a proposition has a binary structure, with one element, the subject, making reference to an entity and the other expressing a property, and (b) the semantic idea that asserting a proposition involves an act of asserting that an object, the reference of the subject argument, has a property expressed by the predicate. Thus, an assertion of *John is happy* is true if the denotation of the subject argument *John* has the property expressed by the predicate *is happy*.

The concept of predication played a central role in traditional grammatical discourse, and the division of a sentence into subject and predicate, became a commonplace of traditional parsing techniques. However, an understanding of what a subject and predicate actually might be waited until the techniques of modern logic and linguistics, when two questions in particular came to the center of the discussion. The first is the question of why the predication relation is so important, which could be discussed only after Frege had formulated his distinction between saturated and unsaturated linguistic entities. The second question is why one referential argument, the subject, has a privileged or distinguished position in the sentence, and progress on this point had to wait for the structural tools of modern generative syntax. This issue in fact never arose for Aristotle, since he dealt only with single-argument sentences such as *The ship sailed*, but it arises as soon as we look at sentences such as *The sailors sailed the ship*.

The major breakthrough for predication (and in fact semantics in general) came with the work of Frege at the end of the 19th century. Frege drew the distinction between saturated and unsaturated expressions. A formally unsaturated expression is an expression that contains an empty position filled by a variable, as in the mathematical expression $x + 2$, whereas a saturated expression is one that we naturally think of as denoting an object (for Frege, either an individual or a truth value). An unsaturated expression, or function, applies to a saturated expression or argument and yields a value or an output. Thus $x + 2$ applies to an argument, for example 3, to yield a value that is the denotation of the saturated expression. In this case, the value of the saturated expression $3 + 2$ is the same as the denotation of 5.

Frege saw that linguistic expressions could be analyzed in the same way. The expression *The capital city of x* can be analyzed as a function that has as its denotation, or value, a different city depending on which name replaces the variable *x*. *The capital city of Germany* denotes Berlin and *The capital city of the UK* denotes London. Similarly, a predicate such as *x is happy* can be applied to an argument expression

Predication

S Rothstein, Bar-Ilan University, Ramat Gan, Israel

The predication relation was introduced into discourse about language by Aristotle in 'On Interpretation,' (paragraphs 5 and 6) when he defined a proposition as an instance of predication, which "asserts or denies something of something." He thus introduced into philosophical and linguistic discussion two central ideas: (a) the syntactic idea that a proposition has a binary structure, with one element, the subject, making reference to an entity and the other expressing a property, and (b) the semantic idea that asserting a proposition involves an act of asserting that an object, the reference of the subject argument, has a property expressed by the predicate. Thus, an assertion of *John is happy* is true if the denotation of the subject argument *John* has the property expressed by the predicate *is happy*.

The concept of predication played a central role in traditional grammatical discourse, and the division of a sentence into subject and predicate, became a commonplace of traditional parsing techniques. However, an understanding of what a subject and predicate actually might be waited until the techniques of modern logic and linguistics, when two questions in particular came to the center of the discussion. The first is the question of why the predication relation is so important, which could be discussed only after Frege had formulated his distinction between saturated and unsaturated linguistic entities. The second question is why one referential argument, the subject, has a privileged or distinguished position in the sentence, and progress on this point had to wait for the structural tools of modern generative syntax. This issue in fact never arose for Aristotle, since he dealt only with single-argument sentences such as *The ship sailed*, but it arises as soon as we look at sentences such as *The sailors sailed the ship*.

The major breakthrough for predication (and in fact semantics in general) came with the work of Frege at the end of the 19th century. Frege drew the distinction between saturated and unsaturated expressions. A formally unsaturated expression is an expression that contains an empty position filled by a variable, as in the mathematical expression $x + 2$, whereas a saturated expression is one that we naturally think of as denoting an object (for Frege, either an individual or a truth value). An unsaturated expression, or function, applies to a saturated expression or argument and yields a value or an output. Thus $x + 2$ applies to an argument, for example 3, to yield a value that is the denotation of the saturated expression. In this case, the value of the saturated expression $3 + 2$ is the same as the denotation of 5.

Frege saw that linguistic expressions could be analyzed in the same way. The expression *The capital city of x* can be analyzed as a function that has as its denotation, or value, a different city depending on which name replaces the variable *x*. *The capital city of Germany* denotes Berlin and *The capital city of the UK* denotes London. Similarly, a predicate such as *x is happy* can be applied to an argument expression

such as *John* or *the boy* to yield a sentence, which has the value true or false, depending on whether or not John is or is not happy.

Frege's insight that complex expressions could be built up compositionally from simple saturated and unsaturated expressions, by a recursive process of functional application, was at the root of much progress in logic and semantics, as can be seen in the work of Montague (1970) and the formal semanticists who followed, and the work of Bar-Hillel and the categorial grammarians, all of whom focused on issues of compositionality. The issue of predication entered the syntactic discourse through the seminal work of Halliday (1967), who drew attention to secondary predicates, which were predicated of and expressed properties of local subjects, rather than sentential subjects. Halliday (1967) brought to the attention of linguists that predicative adjectives occurred with quite a limited range of meanings in constructions such as (1), and that the relation between the predicate and its local subject (in bold and italics, respectively) mirrored the semantic relation between the predicate of a sentence and the sentential subject, in the sense that if the sentence asserted was true, the subject had to have the property expressed by the predicate.

(1a) Mary painted the *house* **red**.
(1b) *John* drove the car **drunk**.
(1c) John drove *the car* **broken.**

Example (1a) is an instance of resultative predication, with the AP predicate expressing a property that the subject is asserted to have at the end of the action expressed by the verbal predicate; (1b) and (1c) are examples of depictive predication, with the AP predicate expressing a property that the subject is asserted to have while the action expressed by the verbal predicate is going on. Resultatives are typically predicated of direct object arguments, while depictives, as the examples in (1) show, may be predicated of subject or direct object arguments.

It was Edwin Williams, who in a series of papers (Williams, 1980, 1983, 1987) brought predication into the domain of generative syntax. Although there had been quite a lot of discussion around the notion of subject, Williams was the first to tie it into a discussion of the subject predicate relation. For him, the central questions were how to explain the syntactic relation of a secondary predicate to its subject (in more modern theoretical language, to explain how the predicate AP is licensed, or integrated into the structure of the sentence), how to explain why the subject argument is distinguished, and how to draw the appropriate structural parallels between secondary and main clause predicates. He argued that predication is essentially a thematic relation, and that the syntactic predication relation was expressed via the assignment of thematic roles. A lexical head assigns thematic roles to its thematic arguments, and in general all but one of the thematic arguments is assigned to an argument syntactically realized inside the projection of the thematic head. The thematic role assigned outside the projection of the head is external. Williams argued that the subject of a predicate is the argument assigned an external argument, and the primacy of the subject follows from the basic syntactic distinction between external and internal arguments. Thus, in a sentence such as (1a), assigned the structure in (2), the adjective *red* assigns a thematic role outside the maximal AP projection that it heads to *the house* and that therefore is its subject. Williams showed that this mechanism of external theta-role assignment could be used to express sentential subject predicate relations also. In (1a), *Mary* is assigned a thematic role 'agent' by *paint* outside the VP projection of the head, and is thus the subject of the whole predicate *paint the house red*.

(2)

What Williams captured precisely in this account is the duality of the relation between the sentential subject and the verb: the subject is a thematic argument of the verb, but subject of the whole predicate phrase that the verb heads. Williams was not explicit about the semantic interpretation of the predication relation, but he assumes that the adicity of the lexical head (the number of thematic roles it assigns) directly reflects the adicity of a semantic relation denoted by the lexical head and that thematic role assignment is a syntactic reflection of a semantic relation. Williams was thus making implicit use of Frege's classification of linguistic objects into saturated and unsaturated. This became explicit in Williams (1987), where he presents an account of the mapping between syntactic representation and semantic representation, where he argues that unassigned thematic roles are interpreted as unsaturated variables in the semantic representation. Furthermore, argument traces (NP, or rather DP, traces) are to be analyzed as variables in the same way, and thus NP movement is ultimately reducible to the predication relation.

Rothstein (1983) and later Rothstein (1995, 2001) followed Williams in identifying predication as a

central mechanism in syntactic theory, but argued against identifying syntactic unsaturatedness with unassigned thematic roles. She argued that in order to analyze a sentence generally as an instance of a predication relation, it is necessary to recognize cases of predication that do not involve a thematic relation between the head of the predicate and the subject. This is because of the existence of pleonastics, or nonthematic subjects, examples of which are given in (3):

(3a) It seems that John will not arrive on time.
(3b) Il a été mangé trois pommes. (French)
it has been eaten three apples.
'Three apples have been eaten.'
(3c) ze meatzben Se dani meaxer. (Hebrew)
it irritates that dani is late.
'It is irritating that Dani is late.'

Rothstein argued that the Fregean saturated/unsaturated distinction is a primitive typal syntactic distinction between two different kinds of syntactic constituents: arguments and predicates. The typically referential constituents, DP and CP, are syntactically saturated and canonically serve as arguments, while the AP, PP, VP, and NP constituents are inherently unsaturated and can serve as predicates. Unsaturated constituents are typically saturated either directly or indirectly by predication (although NP arguments are saturated via determiner binding when they appear in argument position). Crucially, the syntactic relation between the pleonastic subject *it* in (3a) and the VP *seems that John will not arrive on time* is exactly the same predication relation as holds between the subject *John* and predicate *is happy* in the sentence *John is happy*. Rothstein argued that under this analysis, the distribution of pleonastic subjects in English could be completely predicted, and that the obligatoriness of the subject (expressed in Chomsky's 1982 Extended Projection Principle) could be explained. In particular, she gave an account of the obligatoriness of the pleonastic in complement position of verbs such as *consider*, illustrated in (4a), in which she argues that pleonastics appear as the subject of small clause predications, and of the optional movement of CP direct objects to subject position illustrated in (4b):

(4a) I consider it ridiculous that John is late again.
(4b) It has long been believed that the earth is flat.

In this approach, thematic subjects are just a proper subset of subjects, and thematic role assignment to subject position uses the predication relation, just as thematic role assignment to internal arguments is via Case assignment relations or prepositions. Rothstein argued that there were two different kinds of predication: primary, or clausal, predication and secondary, or adjunct, predication. The particular constraints on adjunct predication (see Rothstein, 2003) mean that secondary predicates are essentially thematic, while primary predication need not be so.

Another approach to predication, which starts from different assumptions, but has some of the same syntactic consequences as Rothstein's, is Gennaro Chierchia's. Working within the framework of property theory, he proposed treating semantic properties as having two modes of presentation, an unsaturated predicate and its individual property correlate, π. He is concerned primarily with semantic issues, in particular, how properties can be predicated of themselves, as in *Being wise is wise* or *Cheerfulness is cheerful*. In Chierchia's theory, a VP denotes a saturated property, and Inflection denotes a function from individual properties into propositional functions, which applies to a VP and yields a propositional function, independently of whether the VP requires a thematic subject. Chierchia differs from Rothstein, who claims that the VP is formally a predicate, and he does not extend his theory to deal with noninflected predicates, but both approaches have in common that the clause is structurally constrained to be an instance of predication, independent of the thematic properties of the predicate or its head. Positing a structural, nonthematic predication relation has been quite fruitful in terms of syntactic explanatoriness. The structural approach to predication has been quite productive in leading to analyses of propositional structure, in particular with respect to the distribution of pleonastics and nonthematic predicates and copula constructions.

A second direction on which predication studies have focused has been the variety and differing properties of secondary predicates crosslinguistically. As mentioned above, there seem to be two kinds of secondary predicates, resultatives and depictives, where resultatives are generally restricted to taking direct objects as their subjects, while depictives can apply to both subjects and objects. Much work has focused on the particular syntactic properties associated with different secondary predicates in different languages, for example with the structural constraints on subject predicate relations (Demonte, 1986), Case properties associated with different secondary predicates (especially in Russian, e.g., Filip, 2001), whether secondary predicates are independent predicates or form a lexical complex predicate with the verb in Germanic (Neeleman, 1994; Neelman and Weerman, 1993; Wunderlich, 1997), whether or not resultatives are truly oriented toward the direct object, (Rappaport Hovav and Levin, 2001; Wechsler, 1997; Kim, 1993), and how best to capture the semantic constraints on

their interpretations. Some of the most interesting syntactic work in recent years has emerged from the attempts to give a unified semantics for depictive and resultative secondary predicates (see, e.g., Rothstein, 2003) and work by Cormack and Smith (1994, 1999), who suggest that secondary predication should be seen as a kind of serial verb construction for languages that do not otherwise allow them. While this idea has not yet been worked out in any detail, it seems a potentially fruitful direction in which to take the syntax of predication.

Prestige, Overt and Covert

Introduction

Most speakers of a language are aware of the fact that there is variation within even quite small speech communities (*see* **Speech Community; Labov, William (b. 1927)**). If they are aware of this variation, they are usually also aware of the fact that different variants are more (or less) appropriate in different social situations. For example, a writer in English has the option of choosing to use *show* or *demonstrate* in a text: The former is associated more with informal and/or spoken modes of delivery, and the latter is more closely associated with more formal and/or academic modes of delivery. Similarly, in Mauritius, Mauritian Creole (Morisyen) is typically used in day-to-day conversations whereas French might be used when taking out a loan at a bank and English would be used in school. Sociolinguists often call the different social contexts in which a language is used different domains and some people use the term 'key' to describe different modes of delivery.

These divisions in domain of use do not index solely the speaker's location. They also index information about the social order of the speech community. Some keys of delivery and some domains are considered to be relatively more prestigious than others. That means that some contexts are more closely tied to evaluations of status within a particular community, and the use of a variant or a language that has greater prestige may confer status on the speaker, the hearer, or both. The use of a high-prestige variant or language also reflexively reconstitutes and perpetuates the association of status and prestige with particular linguistic variants. Defining 'prestige' has been difficult in sociolinguistics, and some definitions have been criticized as being circular. We have to be careful that 'prestige' is not defined as 'a variant that has more status' if the only evidence we have for the variant being statusful is that it is used more by members of a speech community who themselves have more status (e.g., the upper class). If that is our only evidence, then we might more accurately say that we have a variable that is associated with social class rather than with prestige.

There is no deterministic relationship between how old a variable is and whether it has social prestige. Prestige forms can be either older, more conservative variants or newer innovations that are just beginning to take hold in a community. Work in Arabic speech communities highlights this point neatly and reminds us that there can be more than one locus of prestige within a speech community. Work by Abd-el-Jawad (1986) and Haeri (1997) showed that the norms of Classical (Standard) Arabic might serve as prestige targets for some speakers in a speech community while the norms of a regional vernacular variety of Arabic might simultaneously constitute the prestigious target for other members of the speech community. This gives rise to the (apparently) paradoxical situation in which different variants occur in the most formal or careful speech of different people in the speech community.

In addition, differences in what is and is not considered 'nice' in different varieties of even the same language illustrate the arbitrariness of what is considered a prestige form. New Zealanders would be quite happy to ask a stranger for directions to the *toilet*, whereas North Americans would prefer to ask for the *bathroom* or *restroom*.

Overt Prestige and the Speech Community

The notion of prestige has been central to advances in sociolinguistics. Labov identified it as a definitional characteristic of a speech community. He argued that a speech community is made up not only of people who use the same variants, but – crucially – of people who shared the same evaluations of those variants. That is, comembers of a speech community agreed on what forms were more or less prestigious or appropriate in different domains or in different modes of delivery. It is important to note that they might not be overtly aware of their shared perceptions. Labov's point about shared evaluations was made in relation to speakers' subconscious shifts in style as well as stereotypes that were more widely available for social comment. In this way, he provided a methodology for avoiding the circularity previously mentioned.

In other words, prestige forms might be widely recognized within a community of speakers, or the fact that they are prestigious might show up only in the subtle and unplanned manner in which speakers change their pronunciations of different words in different contexts and with different addressees. Most speakers of British English can tell you that it is in some sense 'better' not to drop /h/ word-initially, for example, in *house* and *hurt* (even though they may frequently do so themselves). The /h/-less forms lack prestige and are considered informal, uneducated, or even lower-class and vulgar.

On the other hand, a lot of native speakers of English are very confused about what the appropriate

form is for a coordinated object phrase, as shown in (1) (Angermeyer and Singler, 2003: 189).

(1) There's a whole world for **you and I**. Or is it **you and me**? Does anybody know?

Angermeyer and Singler found a clever experimental way of supplementing their observations of natural occurrences of these kinds of utterances. They show that the *you and I* forms occur more often when speakers are monitoring their speech than when they are speaking informally, so we would say that, for speakers of U.S. English, the *you and I* forms are perceived to be better or to have more prestige than the (prescriptively correct) *you and me* or *me and you*.

A famous example illustrating the interaction between how carefully or consciously a speaker is focusing on his or her speech and his or her use of different forms was provided by Labov's study of the New York City vernacular. He showed that speakers from all social classes used more of the (innovative) prestige variant /r/ in the artificial context of reading a word list than they did in casual speech. Figure 1 shows the frequency with which different social classes in New York City used the in-coming variant /r/ word-finally (as in *car*) or preconsonantally (as in *card*).

In casual speech, use of the /r/ variant was almost entirely restricted to the middle-middle-class speakers (SEC 9) and did not occur in any of the other classes with very high frequency (0% in SEC 0–1, 3% in SEC 2–5, and 2% in SEC 6–8). However, when reading word lists, all speakers used a lot more of the in-coming, prestigious variant, and the speakers in SEC 6–8, the lower middle class, used it most of all the groups (almost categorically at 90%). Labov found very similar patterns for variables like (r) and other changes happening well below speakers' conscious awareness, such as the raising of short (a) in *bad*, and *ask*.

Crossover Effect or Hypercorrection

Figure 1 also illustrates a phenomenon known as the crossover effect, or hypercorrection. This refers to the way that SEC 6–8 (the lower middle class) uses even more of the prestige variant /r/ when reading a word list than SEC 9 (the upper middle class) do. In general, even if we break the data down into even narrower bands of SECs, the different classes are clearly stratified with respect to their use of the (r) variable. 'Stratification' means that the results for speakers from different SECs appear to form discrete layers; in all the different speaking styles, speakers from lower SECs use fewer tokens of the prestige variant than speakers from higher SECs. However, in Figure 1, the speakers in SEC 6–8 cross over the speakers from SEC 9 in word-list style. In this style, speakers from a lower SEC use more of the prestige variants than speakers from a higher SEC. Labov suggested that speakers from the second highest SEC may be especially sensitive to the social value of linguistic variables and the social returns available to them through using particular variants. The crossover effect observed in Figure 1 is a manifestation of this heightened awareness. When members of the second highest social class are performing linguistic tasks that focus them more or less directly on language itself, they draw more often on the markers of prestige within the speech community.

The term 'hypercorrection' has also been applied to the crossover effect shown in Figure 1. Hypercorrection originally referred to situations in which speakers emend a standard pronunciation of a word

Figure 1 Frequency of use of /r/ in final and preconsonantal position in New York City in four socioeconomic class groupings. SEC, socioeconomic class; 0 = lowest; 9 = highest. (Based on Labov, 1972: Tables 9.5 and 9.6.)

because they mistakenly perceive it to be nonstandard or an error. This is often due to the imperfect learning of a new language or dialect. In some varieties of English, speakers seldom use [ɪŋ] in words such as *talking* or *choosing,* but they may still be aware that these forms are widely considered 'better' than pronunciations with the alveolar variant [ɪn]. However, because their own vernacular provides them with few models of the prestige forms, they may end up using the prestige form in places where it never occurs in any variety of English. For example, in Thackeray's (1998) *Vanity Fair,* a lower-class character is lampooned for talking about his army *Captaing* [æptɪŋ] (not [æptɪn]). What a speaker perceives to be the 'correction' of a nonstandard, or vulgar, form may produce something that is not actually attested in any native variety of English. For this reason, it is called **hyper**correction.

The lower-middle-class crossover effect observed by Labov is a little different than this because what is produced is still clearly part of the speech community's norms. The speakers' behavior can really only be called hypercorrect if we assume that social class has a strongly deterministic effect on speech. For these reasons, hypercorrection is not the best term to describe this phenomenon, and the more descriptive term crossover is to be preferred.

Covert Prestige

We have seen that speakers may be oriented to prestige norms in a speech community with more or less conscious awareness. It is also clear that people do not always use the forms that are widely recognized as being prestigious. Generally, what might be appropriate in a formal spoken or written exchange is not so appropriate when we are talking to our best friends or family. Speakers are aware that prestige is relative to different situations and addressees and know that, if they use words or pronunciations that have high prestige in formal contexts in an informal domain, they will be ridiculed or disliked. German speakers generally switch between their local vernacular dialect, with its characteristic pronunciations and lexical items, used when they are talking at home, and Standard German (*Hochdeutsch*), used when they are speaking in public or writing. Of course, the qualities of naturalness and directness that are often associated with the vernacular have their own prestige, as do the rougher, street-wise qualities that are often also associated with the vernacular. This kind of prestige can be strategically drawn on, as when politicians wants to present themselves as 'one of the people.'

This kind of alternative, local form of prestige is sometimes – wrongly – called 'covert prestige' (as opposed to the overt prestige that members of a speech community are openly oriented to). The term 'covert prestige' was originally introduced into sociolinguistics to describe a rather more subtle effect than the persistence of nonstandard or vernacular varieties. Trudgill's early work used subjective attitude tests to inform the analysis of speakers' objective performance, and he observed that some speakers recognize the overt prestige of a certain form and that they may indeed use that form more often than the less prestigious one. However, they may claim that they use the less prestigious variant. That is, their objective performance (what they say) is oriented to the wider socially prestigious form, whereas their subjective report of their performance is oriented to a local variant. Trudgill considered this mismatch between what the speakers say they do and what they actually do as evidence that some forms have covert prestige.

Presupposition

Introduction

A presupposition is a semantic property of a sentence making that sentence fit for use in certain contexts and unfit for use in others. This property is partly based on the fact that if a sentence B presupposes a sentence A ($B \gg A$), then B entails A ($B \models A$): whenever B is true, A is necessarily also true, given the same situation referred to, in virtue of the *meanings* of B and A. Presuppositions (*P-entailments*) are thus a subclass of entailments. Entailments that are not presuppositional are *classical* or *C-entailments*. (1) illustrates a C-entailment ($\models_c$); (2a–d) illustrate P-entailments ($\gg$):

(1) Jack has been murdered. $\models_c$ Jack is dead.

(2a) Jack lives in Manchester. $\gg$ Jack exists.
(2b) Jill has forgotten that Jack is her student. $\gg$ Jack is Jill's student.
(2c) Jack is divorced. $\gg$ Jack was once married.
(2d) Only Jack left. $\gg$ Jack left.

(2a) illustrates *existential presupposition*. (2b) exemplifies *factive presuppositions* (Kiparsky and Kiparsky, 1971): the factive predicate (*have forgotten*) requires the truth of the *that*-clause. (2c) is a case of *categorial presupposition*, derived from the lexical meaning of the main predicate (*be divorced*). (2d) belongs to a *remainder category*, the presupposition in question being due to the particle *only*.

There are various differences between P-entailments and C-entailments. When $B \gg A$, A is somehow 'prior' to B, restricting the domain within which B is interpretable. Presuppositions present themselves specifically, whereas C-entailments are 'unguided' and thus lack the function of restricting the interpretation domain. This makes presupposition relevant for the cognitive aspects of linguistic information transfer.

There is also a logical difference, especially regarding *negation*, the central operator in any logic. In standard logic a sentence that is false for any reason whatsoever is made true by the preposed negation. In language, however, negation is sensitive, in default uses, only to C-entailments, leaving the P-entailments intact. Suppose (2d) is false on account of a C-entailment's falsity, for example because other people left as well. Then (3a), the negation of (2d), is true and (3b) is coherent, as expected. Not so when a P-entailment of (2d) is false, as in (3c), where the presupposition 'Jack left' is denied. (3c) is incoherent because *Not only Jack left* still presupposes that Jack left ('!!' indicates incoherence):

(3a) Not only Jack left.
(3b) Not only Jack left: other people left as well.
(3c) !!Not only Jack left: Jack did not leave.

This raises the question of the truth value of (3a) in cases where, say, Jack did not leave. In standard logic, the entailment from both (2d) and its negation (3a) to *Jack left* means that if Jack did not leave, both (3a) and (2d) are false simultaneously, which violates the Principle of Contradiction ('a sentence and its negation cannot be true or false simultaneously'). Standard logic thus rules out falsity for *Jack left*, because its falsity leads to a contradiction. This makes *Jack left* a necessary truth. But *Jack left* is, if true, contingently so. Therefore, standard logic is inadequate for presuppositions.

Many feel that this calls for a rejection of the Principle of the Excluded Third or PET ('any sentence expressing a proposition is either true or false, without any values in between or outside') and for the introduction of a *third truth value* into the logic of language. Others prefer to keep standard bivalent logic intact and seek a *pragmatic* way out in terms of conditions of use. This question is discussed in the next section.

Operational Criteria

Presuppositions are detectable ('observable') irrespective of actual token use. Like C-entailments, P-entailments can be read off isolated sentences, regardless of special context. Yet they evoke a context. (2a) requires it to be contextually given that there exists someone called 'Jack' and thus evokes such a context, asserting that he lives in Manchester; (2b) evokes a context where Jack is Jill's student, asserting that Jill has forgotten that; (2c) requires a context where Jack was once married, and asserts that the marriage has been dissolved; and (2d) requires a context where Jack left, while asserting that no one else left. This, together with the entailment criterion, provides a set of operational criteria to recognize presuppositions.

First, if $B \gg A$ then $B \models A$. The usual heuristic criterion for an entailment $B \models A$ is the incoherence of the juxtaposition of *not(A)* with B. On the whole, this suffices as a criterion. For example, (4a) does not entail, and therefore does not presuppose, (4b), because (4c) is still coherent.

(4a) Lady Fortune neighs.
(4b) Lady Fortune is a horse.
(4c) Lady Fortune is not a horse, yet she neighs.

But this criterion overkills when the entailing sentence is qualified by an epistemic possibility operator, like English *may*, as in (5a), which does not entail (5b), even though (5c) is incoherent. Epistemic possibility requires compatibility of what is said to be possible with what is given in discourse or knowledge. Therefore, if $B \models A$, then with *not(A)* in the knowledge base, *possibly(B)* results in inconsistency, although *possibly(B)* does not entail *A*. The entailment criterion can be refined, without loss of generality, by testing the (in)coherence of the juxtaposition of *possibly (not(A))* with *B*, as in (5d). Because (5d) is coherent, (5a) $\not\models$ (5b):

(5a) Jack may have been murdered.
(5b) Jack is dead.
(5c) !! Jack is not dead, yet he may have been murdered.
(5d) Jack may not be dead, yet he may have been murdered (and thus be dead).

To distinguish P-entailments from C-entailments further criteria are needed. First there is the *projection criterion*: if $B \gg A$ and *B* stands under an entailment-canceling operator like *possibly* or *not* or *believe*, *A* survives not as a P-entailment but as a more or less strongly invited presuppositional inference (>). Generally, $\mathbf{O}(B_A) > A$, where 'B_A' stands for '*B* presupposing *A*' and '**O**' for an entailment-canceling operator. In standard terminology, the presupposition *A* is *projected* through the operator **O**. The conditions under which presuppositions of embedded clauses are projected through higher operators constitute the *projection problem of presupposition*.

Projection is typical of P-entailments, as in (6), not of C-entailments, as in (7):

(6) Jill believes that Jack is divorced > Jack was once married.

(7) Jill believes that Jack has been murdered $\not>$ Jack is dead.

The projection criterion is mostly used with negation as the entailment-canceling operator. Strawson (1950, 1952) held, incorrectly, that presupposition is always preserved as entailment under negation. In his view, a sentence like:

(8) The present king of France is not wise.

still presupposes, and thus entails, that there exists a king of France, who therefore, if (8) is true, must lack wisdom. Although presupposition is, in fact, normally weakened to invited inference under negation, Strawson's 'negation test' became the standard test for presupposition. Provided the condition of 'entailment' is replaced by that of 'at least invited inference,' the test is sound.

Then there is the *discourse criterion*: a discourse bit *A and/but* B_A (with allowance for anaphoric processes) is felt to be orderly and well planned – that is, *sequential*. The condition of sequentiality is used to characterize stretches of acceptable text that have their presuppositions spelled out ('√' signals sequentiality):

(9a) √There exists someone called 'Jack,' and he lives in Manchester.
(9b) √Jack is Jill's student, but she has forgotten that he is.
(9c) √Jack was married, but he is divorced.
(9d) √Jack left, and he is the only one who did.

C-entailments and inductive inferences behave differently. When they precede their carrier sentence the result may still be acceptable, yet there is a qualitative difference, as shown in (10a,b), where a colon after the first conjunct is more natural ('#' signals nonsequential but coherent discourse):

(10a) #Jack is dead: he has been murdered.
(10b) #Jack earns money: he has a job now.

The discourse criterion still applies through projection: *A and/but* $\mathbf{O}(B_A)$ is again sequential (the entailment-canceling operators are printed in italics):

(11a) √Jack really exists, and Jill *believes* that he lives in Manchester.
(11b) √Jack is Jill's student, but she has *probably* forgotten that he is.
(11c) √Jack was once married, and he is *not* divorced.
(11d) √Jack left, and he is *not* the only one who did.

These tests reliably set off P-entailments from C-entailments.

The Logical Problem

The Threat to Bivalence

The first to see the threat posed by presuppositions to standard logic was Aristotle's contemporary Eubulides of Miletus (Kneale and Kneale, 1962: 113–117). He formulated (besides other paradoxes such as the Liar) the paradox of the *Horned Man* (Kneale and Kneale, 1962: 114): "What you have not lost you still have. But you have not lost your horns. So you still have horns." This paradox rests on presupposition. Read *B* for *You have lost your horns* and *A* for *You had horns*. Now $B \gg A$ (the predicate *have lost* induces the presupposition that what has been lost was once possessed).

Eubulides implicitly assumed that P-entailments are preserved under negation: $B \models A$ and *not(B)* $\models A$. Under PET, this would make *A* a logically necessary

truth, which is absurd for a contingent sentence like *You had horns*. To avoid this, PET would have to be dropped, very much against Aristotle's wish. Although Aristotle himself was unable to show Eubulides wrong, there is a flaw in the paradox. It lies in the incorrectly assumed entailment in the first premise "What you have not lost you still have." For it is possible that a person has not lost something precisely because he never had it.

The same problem was raised by Strawson (1950, 1952), but with regard to existential presuppositions. Like Eubulides, Strawson assumed full entailment of presupposition under negation and concluded that PET had to go. For him, nonfulfillment of a presupposition leads to both the carrier sentence and its negation lacking a truth value altogether. Frege (1892) had come to the same conclusion, though from a different angle. In a sentence like:

(12) The unicorn ran.

analyzed as 'Run(the unicorn)', the subject term lacks a referent in the actual world, though the existence of such a referent is presupposed. That makes it impossible to test the truth of (12): since there is no unicorn, there is no way to check whether it actually ran. Therefore, Frege (and Strawson) concluded, (12) lacks a truth value.

This posed a profound problem for standard logic in that the applicability of standard logic to English would have to be made dependent on contingent conditions of existence – a restriction no logician will accept. In the effort to solve this problem two traditions developed, the *Russell tradition* and the *Frege–Strawson tradition*.

The Russell Tradition

In his famous 1905 article, Russell proposed a new analysis for sentences with definite terms, like (13a). Putting the new theory of quantification to use, he analyzed (13a) as (13b), or 'there is an individual *x* such that *x* is now king of France and *x* is bald, and for all individuals *y*, if *y* is now king of France, *y* is identical with *x*':

(13a) The present king of France is bald.
(13b) $\exists x\ [KoF(x) \wedge Bald(x) \wedge \forall y\ [KoF(y) \rightarrow x = y]]$

In order to save bivalence, Russell thus replaced the time-honored subject-predicate analysis with an analysis in which the definite description *the present king of France* no longer forms a constituent of the logically analyzed sentence, but is dissolved into quantifiers and propositional functions.

The negation of (13a) should be (13b) preceded by the negation operator, i.e. (14a). However, Russell held, speakers often prefer, for reasons best known to themselves, to interpret *The present king of France is not bald* as (14b), with internal negation over 'Bald(x)':

(14a) $\neg\exists x\ [KoF(x) \wedge Bald(x) \wedge \forall y\ [KoF(y) \rightarrow x = y]]$
(14b) $\exists x\ [KoF(x) \wedge \neg Bald(x) \wedge \forall y\ [KoF(y) \rightarrow x = y]]$

This makes sentences like (8) ambiguous.

This analysis, known as Russell's *Theory of Descriptions*, was quickly accepted by logicians and philosophers of language, as it saved PET. At the same time, however, it drove logicians and linguists apart, as it defies any notion of sentence structure. Moreover, the 'uniqueness clause' in (13b), $\forall y\ [KoF(y) \rightarrow x = y]$, saying that only one king of France exists, is meant to account for the uniqueness expressed by the definite article. In fact, however, the definite article implies no claim to uniqueness of existence, only to discourse-bound uniqueness of reference. Then, this analysis is limited to definite descriptions and is unable to account for other kinds of presupposition. Factive and categorial presuppositions, and those derived from words like *all*, *still*, or *only*, fall outside its coverage.

An important objection is also that negation can only cancel presuppositions when it is a separate word (not a bound morpheme) and in construction with a finite verb. In all other cases, the negation fully preserves P-entailments. Thus, (3a), with *not* in construction with *only*, preserves the presupposition induced by *only*. Moreover, sentence-initial factive *that*-clauses preserve presuppositions even though the negation is constructed with the finite verb:

(15a) That Jack left surprised Jill $\gg$ Jack left.
(15b) That Jack left did not surprise Jill $\gg$ Jack left.

Likewise for cleft and pseudocleft sentences:

(16a) It was Jack who left / The one who left was Jack $\gg$ Someone left.
(16b) It wasn't Jack who left / The one who left wasn't Jack $\gg$ Someone left.

When cases like these, overlooked by the authors discussed, are taken into account and the logic is kept bivalent, the presuppositions of sentences like (2d) and (3a), (15a,b), or (16a,b) would again have to be necessary truths.

The same goes for:

(17a) All men are mortal $\gg$ There exist men.
(17b) Not all men are mortal $\gg$ There exist men.

In standard Predicate Calculus, however, (17a) does not entail (and thus cannot presuppose) that there exist men, whereas (17b) does, because 'not all F is G' is considered equivalent with 'some F is not G,'

which entails the existence of at least one F. Yet both (17a) and (17b) satisfy the operational criteria given earlier. Standard Predicate Calculus thus seems to fit the presuppositional facts badly.

To account for other than existential presuppositions some have proposed to change Russell's analysis into:

(18) $\exists x\ [KoF(x)] \wedge Bald(he)$

or 'there is a king of France, and he is bald'. *He* is now no longer a bound variable but an anaphoric pronoun. With a logical mechanism for such anaphora (as in Kamp, 1981; Groenendijk and Stokhof, 1991), this analysis can be generalized to all categories of presupposition. A sentence B_A is now analyzed as *A and* B_A, and *Not*(B_A), though normally analyzed as *A and Not*(B_A) with small scope *not*, can also, forced by discourse conditions, be analyzed as *Not (A and* B_A*)*, with large scope *not*. This analysis, which saves PET, is known as the *Conjunction Analysis* for presupposition.

Anaphora is needed anyway, because Russell's analysis fails for cases like (19), where quantifier binding is impossible for *it*, which is in the scope of *I hope*, whereas *I hope* is outside the scope of *I know*:

(19) I know that there is a dog and I hope that it is white.

The Conjunction Analysis, however, still cannot account for the fact that (20a) is coherent but (20b) is not:

(20a) There is a dog and it is white, and there is a dog and it is not white.
(20b) !!There is a dog and it is white and it is not white.

(20a) speaks of two dogs, due to the repetition of *there is a dog*, but (20b) speaks of only one. Yet the Conjunction Analysis cannot make that difference, because the repetition of *there is a dog* makes no logical or semantic difference for it. Attempts have been made to incorporate this difference into the logic (e.g., Kamp, 1981; Heim, 1982; Groenendijk and Stokhof, 1991) by attaching a memory store to the model theory that keeps track of the elements that have so far been introduced existentially.

Even then, however, the Conjunction Analysis still postulates existence for term referents whose existence is denied:

(21) Santa Claus does not exist.

The Frege-Strawson Tradition

Strawson (1950, 1952) was the first to oppose the Russell tradition. He reinstated the traditional subject-predicate analysis and discussed only existential presuppositions. Negation is considered presupposition-preserving. Sentences with presupposition failure are considered truth-valueless. Strawson's definition of presupposition is strictly logical: $B \gg A =_{Def} B \models A$ and *Not(B)* $\models A$. This analysis requires a *gapped bivalent propositional calculus* (GBPC), shown in Figure 1.

		∧ B			∨ B		
~A	A	T	F	*	T	F	*
F	T	T	F	*	T	T	*
T	F	F	F	*	T	F	*
*	*	*	*	*	*	*	*

Figure 1 Strawson's gapped bivalent propositional calculus (GBPC). Key: ~, presupposition-preserving negation; T, truth; F, falsity; *, unvalued.

Insofar as truth values are assigned, GBPC preserves standard logic. Moreover, * is 'infectious': when fed into a truth function it yields *. Remarkably, GBPC limits the applicability of logic to situations where the presuppositions of the sentences involved are true. The applicability of GBPC thus varies with contingent circumstances.

Wilson (1975) and Boër and Lycan (1976) side with Russell and criticize Strawson, showing examples of presupposition-canceling under negation: (22a–c) are coherent, though they require emphatic, discourse-correcting accent on *not*:

(22a) The present king of France is NOT bald: there is no king of France!
(22b) Jill has NOT forgotten that Jack is her student: Jack isn't her student!
(22c) Jack is NOT divorced: he never married!

For these authors, classical bivalent logic is adequate for language; P-entailments differ from C-entailments only pragmatically. There would be a point if (a) a pragmatic explanation were available, and (b) presuppositions were always canceled under negation. But neither condition is fulfilled. In fact, the presupposition-canceling 'echo' negation NOT of (22a–c) is impossible for cases that preserve P-entailments under negation:

(23a) !!NOT only Jack left: he didn't leave!
(23b) !!NOT all students protested: there weren't any students!
(23c) !!That Jack left did NOT surprise Jill: he didn't leave!
(23d) !! The one who left was NOT Jack: nobody left!

Likewise for the negation required with *negative polarity items* (NPIs) in assertive main clauses (NPIs are printed in italics):

(24a) !!Jack does NOT *mind* that he is in trouble: he isn't in trouble!
(24b) !!Jack has NOT come back *yet*: he never went away!
(24c) !!Jill has NOT seen Jack *in weeks:* she doesn't exist!

This analysis is thus fatally flawed.

The Trivalent Solution

One may envisage a three-valued logic, identical to standard bivalent logic but for a distinction between two kinds of falsity, each turned into truth by a separate negation operator. Minimal falsity (F1) results when all P-entailments are true but not all C-entailments, radical falsity (F2) when one or more P-entailments are false. Correspondingly, *minimal negation* ($\sim$) turns F1 into truth (T) and T into F1, leaving F2 unaffected, whereas *radical negation* ($\simeq$) turns F2 into T and both T and F1 into F1.

In Kleene's (1938) *trivalent propositional calculus*, $\wedge$ yields T only if both conjuncts are T, F1 when either conjunct is F1, and F2 otherwise. Analogously, $\vee$ yields T when either conjunct is T, F1 only if both conjuncts are F1, and F2 otherwise. The corresponding tables are given in Figure 2 (*see* **Multivalued Logics**, where the value F2 is named 'indefinite' or I). This logic preserves all theorems of standard logic when bivalent $\neg$ replaces trivalent $\sim$. Kleene's calculus lacks the radical negation ($\simeq$), but comes to no harm if it is added.

Kleene's calculus is used by some presuppositional logicians (e.g., Blau, 1978). It is empirically problematic in that it yields F1 for 'A $\wedge$ B' when either *A* or *B* is F2 whereas the other is F1, thus allowing presupposition failure in one conjunct while still considering the conjunction as a whole free from presupposition failure. This makes no sense in view of *and* as a discourse incrementer. Kleene's calculus is more suitable for vagueness phenomena with F2 as an umbrella value for all intermediate values between T and F (Seuren *et al.*, 2001).

In Seuren's presuppositional propositional calculus TPC2 (Seuren, 1985, 2001: 333–383; Seuren *et al.*, 2001) the operators $\wedge$ and $\vee$ select, respectively, the highest and lowest of the component values (F2 > F1 > T), as shown in Figure 3. Classical negation ($\neg$), added for good measure, is the union of $\sim$ and $\simeq$, but is taken not to occur in natural language, which has only $\sim$ and $\simeq$. In TPC2, F2 for either conjunct yields F2 for 'A $\wedge$ B', as required.

TPC2 is likewise equivalent with standard bivalent logic under the operators $\neg$, $\wedge$, and $\vee$ (Weijters, 1985). Thus, closed under ($\neg$, $\wedge$, $\vee$) standard bivalent logic is independent of the number of truth values

			$\wedge$ B			$\vee$ B		
¬A	~A	A	T	F1	F2	T	F1	F2
F1	F1	T	T	F1	F2	T	T	T
T	T	F1	F1	F1	F1	T	F1	F2
T	F2	F2	F2	F1	F2	T	F2	F2

Figure 2 Trivalent propositional calculus (TPC1).

				$\wedge$ B			$\vee$ B		
¬A	≃A	~A	A	T	F1	F2	T	F1	F2
F1	F1	F1	T	T	F1	F2	T	T	T
T	F1	T	F1	F1	F1	F2	T	F1	F1
T	T	F2	F2	F2	F2	F2	T	F1	F2

Figure 3 Trivalent propositional calculus (TPC2).

employed, though any value 'false' beyond F1 will be vacuous. Moreover, in both generalizations with *n* truth values ($n \geq 2$), there is, for any value $i \geq 2$, a *specific negation* N^i turning *i* into T, values lower than *i* into F1, and leaving higher values unaffected. Thus, in TPC2, N^{F1} is $\sim$ and N^{F2} is $\simeq$. Classical bivalent $\neg$ is the union of all specific negations. Consequently, in the standard system, $\neg$ is both the one specific negation allowed for and the union of all specific negations admitted. Standard logic is thus the most economical variety possible of a generalized calculus of either type.

The Discourse Approach

Presupposition is not defined, only restricted, by its logical properties:

(25) If $B \gg A$, then $B \models A$ and $\sim B \models A$, and $\sim A / \simeq A \models \simeq B$.

(25) thus specifies necessary, but not sufficient, conditions for presupposition. Were one to adopt a purely logical definition, various paradoxical consequences would follow. For example, any arbitrary sentence would presuppose any necessary truth, which would make the notion of presupposition empirically vacuous.

Attempts have been made (Gazdar, 1979; Heim, 1982; Seuren, 1985, 2000) at viewing a presupposition *A* of a sentence B_A as restricting the interpretable use of *B* to contexts that admit of, or already contain, the information carried by *A*. Such an approach creates room for an account of the discourse-correcting 'echo' function of presupposition-canceling (radical) NOT. Horn (1985, 1989) correctly calls NOT *metalinguistic*, in that it says something about the *sentence* in its scope – though his generalization to other

metalinguistic uses of negation is less certain. Neither TPC2 nor TPC1 can account for this metalinguistic property. This means that the argument of NOT is not a sentence but a quoted sentence. NOT('B_A') says about the sentence B_A that it cannot be sequentially incremented in a discourse refusing *A*.

Sequential incrementation to a discourse **D** restricts **D** to a progressively narrower section of the universe of all possible situations **U**, making the increment *informative*. Incrementation of *A*, or i(A), to **D** restricts **D** to the intersection of the set of situations in which **D** is true and the set of situations where *A* is true. The set of situations in which a sentence or set of sentences X is true is the *valuation space* of X, or /X/. For **D** incremented with *A* we write '$\mathbf{D}+A$'. $\mathbf{D}+A$ is the conjunction of **D** and *A*, where **D** is the conjunction of all incremented sentences since the initial **U**. The *sequentiality condition* requires:

(a) for any *A*, /**D**/ is larger than /$\mathbf{D}+A$/ (informativity: remember that **D** is restricted by *A*);
(b) if $B \gg A$ then i(A) must precede i(B) (not so when $B \models_c A$).

If *A* has not already been incremented prior to i(BA) it is cognitively 'slipped in,' a process called *accommodation* or *post hoc suppletion*. A text requiring accommodation is not fully sequential, but still fully coherent.

On the assumption that **D**, as so far developed, is true, any subsequent sentence *B* must be valued T or F1, because F2 for *B* implies that some presupposition of *B*, and hence **D** as a whole, is not true. This assumption is made possible by the *Principle of Presumed Truth* (PPT), which says that it must be possible for any **D** to be true. The assumption that **D** is actually true blocks the processing of a new sentence that would be valued F2 in **D**. For example, let **D** contain i(∼A). Now B_A is blocked, because *A* is valued F1 (assuming that **D** is true). But NOT('B') can be incremented and is true under PPT, as it says about *B* that it cannot be incremented.

Therefore, /**D**/ must contain situations with sentences as objects. Cognitively speaking, this is perfectly plausible, because speakers are aware of the fact that they utter words and sentences. That awareness enables them to refer back to words and sentences just uttered or expected to be uttered. Words and sentences as objects are a necessary corollary of any speech utterance. This corollary underlies the free mixing of object language and metalanguage in natural language. The prohibition issued by logicians against such mixing has no ground in natural language (Seuren, 2001: 125–130).

Natural language negation is, in a sense, ambiguous (depending on syntactic conditions) between presupposition-preserving (minimal) *not* and presupposition-canceling (radical) NOT. Many find this unacceptable, because ambiguities are normally language specific, whereas this ambiguity would appear to be universal. Yet the obvious question of what would be the overarching single meaning of the negation in all its uses has not, so far, been answered. Similar problems occur with other logical operators, especially with *and*, *or*, and *if*, as the following examples show:

(26a) Do as I say and you will be a rich man.
(26b) Don't come nearer, or you'll be a dead man.
(26c) That's awful, or should I say 'dreadful'?
(26d) Let's go home, or do you have a better idea?
(26e) If you're tired, I have a spare bed.

In the case of *not* and the other logical operators, speech act factors as well as factors of metalinguistic use play an important role. Unfortunately, the grammar and semantics of both speech acts and metalinguistic use are still largely unexplored. Horn (1985) pointed out that English *not* is often used metalinguistically, as in:

(27a) Not Lizzy, if you please, but the Queen is wearing a funny hat.
(27b) She wasn't happy, she was ecstatic!

And he classifies radical NOT with the other metalinguistic cases. However, as pointed out in Seuren (2001: 345–347), NOT, though metalinguistic, differs from the other cases in that it can only occur in construction with the finite verb (the 'canonical position'), whereas the other metalinguistic negations can occupy any position normal *not* can occur in. (28a) is coherent, with a canonically placed NOT, but (28b,c), likewise with NOT, are incoherent, as NOT is in a non-canonical position:

(28a) He did NOT only lose $500. He only lost $20.
(28b) !!NOT only did he lose $500. He only lost $20.
(28c) !!He NOT only lost $500. He only lost $20.

The question of the overall meaning description of the logical operators, in terms of which their strictly logical meaning would find a place, defines a research project of considerable magnitude – a project that has so far not been undertaken in a coordinated way.

The Structural Source of Presuppositions

The source of at least three of the four types of presupposition distinguished earlier lies in the satisfaction conditions of the main predicate of the carrier sentence. The satisfaction conditions of an *n*-ary predicate P^n are the conditions that must be satisfied

by any *n*-tuple of objects for P^n to yield truth. Thus, for the unary predicate *white* the conditions must specify when any object can truthfully be called 'white'. For the binary predicate *wash* they must specify when it can truthfully be said of any pair of objects <i,j> that '*i* washes *j*'.

A distinction is made between two kinds of lexical conditions, *preconditions* and *update conditions*. When a precondition is not fulfilled, the sentence is radically false; failure of an update condition yields minimal falsity. Fulfillment of all conditions gives truth.

The satisfaction conditions of a predicate P^n are specified according to the schema ([[P^n]] is the extension of P^n):

(29) $[[P^n]] = \{<i^1,i^2,\ldots,i^n> : \ldots(\text{preconditions})\ldots \mid \ldots(\text{update conditions})\ldots\}$
or: 'the extension of P^n is the set of all *n*-tuples of objects $<i^1,i^2,\ldots,i^n>$ such that ... (preconditions) ... and ... (update conditions) ...'.

The satisfaction conditions of the predicate *bald*, for example, may be specified as follows (without claiming lexicographical adequacy):

(30) [[Bald]] = {*i* : *i* is normally covered, in prototypical places, with hair, fur, or pile; or *i* is a tire and normally covered with tread | the normal covering is absent}

This caters for categorial presuppositions. Factive presuppositions are derived by the precondition that the factive clause must be true.

Existential presuppositions are derivable from the precondition that a specific term *t* of a predicate P^n refers to an object existing in the real world. P^n is then *extensional* with respect to *t*. *Talk about*, for example, is extensional with respect to its subject term, but not with respect to its object term, because one can talk about things that do not exist. The satisfaction conditions of *talk about* will thus be as in (31), where the asterisk on *j* indicates that *talk* is nonextensional with respect to its object term:

(31) [[talk about]] = {<i,j*> : ... (preconditions) ... | ... (satisfaction conditions) ... }

The predicate *exist* lacks any preconditions and is to be specified as nonextensional with respect to its subject term:

(32) [[exist]] = { i* | i is an object in the actual world}

A definite subject of the verb *exist* must be represented somewhere in **D**, normally in some intensional subdomain, e.g., the subdomain of things that Jack keeps talking about, as in:

(33) The man that Jack keeps talking about really exists.

The incremental effect of (33) is that the representation of the thing that is said to exist is moved up to the truth domain of **D**. This analysis requires the assumption of *virtual objects* (*see* **Virtual Objects**).

The remainder category of presuppositions, induced by words like *only* or *still*, or by contrastive accent or (pseudo)cleft constructions, looks as if it cannot be thus derived. The choice here is either to derive them by *ad hoc* rules or to adopt a syntactic analysis in terms of which of these words and accents figure as (abstract) predicates at the level of semantic representation taken as input to the incrementation procedure.

Priestley, Joseph (1733–1804)

M S Seegmiller, Montclair St. College, Montclair, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Joseph Priestley (1733–1804) was an English clergyman, scientist, grammarian, educator, and political dissident. Educated as a Calvinist minister, Priestley served as pastor of several congregations in England. Throughout his career, Priestley wrote extensively on a variety of political and theological topics and usually adopted controversial views that brought him into conflict with the authorities and the public. His 1782 book, *History of the corruptions of Christianity*, for example, was publicly burned. He also supported both the American and the French Revolutions. Ultimately, persecution for his views forced him to emigrate to the United States in 1794. He died in Pennsylvania in 1804.

After a meeting with Benjamin Franklin in London, Priestley became passionately interested in scientific experimentation. He contributed important discoveries to the early development of chemistry and electricity, but he will always be remembered for being the 'discoverer' of oxygen who, however, did not recognize what he had discovered.

Through a series of ingenious experiments into the nature of combustion and the chemical properties of gases, Priestley isolated and described many of the properties of oxygen. However, he was so firmly committed to the **phlogiston theory** of combustion (which held that all objects contain a hypothetical substance called phlogiston that is released when the object burns) that he failed to recognize the importance of his discovery. When Priestley communicated the results of his oxygen experiments to Antoine Lavoisier, this French scientist understood their significance and proposed a new theory of combustion that postulated that oxygen played a crucial role (a view that is still held today). Because of this and other work, Lavoisier is considered to be the father of modern chemistry.

Priestley's contribution to the study of language consists of his textbook *The rudiments of English grammar* (hereafter REG), written while he ran a school for boys and girls and published in 1761. Priestley was seeking an effective basis for teaching reading and writing, and his experience as a schoolmaster led him to the conclusion that literacy is best achieved if it is based on the actual usage of the student. Like his writings on politics and religion, REG is characterized by liberalism and common sense. REG proposes that grammar should be determined from everyday usage, not from pronouncements by self-styled experts. While the organization of the book is somewhat traditional, Priestley's unconventional views on grammar make REG an important landmark in the history of grammatical thought.

Primary Progressive Aphasia in Nondementing Adults

O Selnes, Johns Hopkins University School of Medicine, Baltimore, MD, USA
M Harciarek, University of Gdansk, Gdansk, Poland

© 2006 Elsevier Ltd. All rights reserved.

Primary progressive aphasia (PPA) is a focal degenerative condition with decline in one or more language functions and asymmetric atrophy involving the perisylvian regions of the left hemisphere. The clinical syndrome is characterized by a slow, insidious decline in specific aspects of language functioning, with onset typically in the fifth or sixth decade of life. The earliest symptoms are often so subtle that only the patient or family members can detect them. Unlike aphasia due to stroke, the onset is not accompanied by an acute neurological event. Despite gradual worsening of language functions, nonlinguistic aspects of cognition may remain relatively intact for several years. Both a nonfluent variety leading to mutism and a fluent subtype with predominantly semantic impairment are now recognized. Although early cases of focal deterioration of language functions were described by pioneers of aphasia research such as Arnold Pick (Luzzatti and Poeck, 1991), it was Mesulam who proposed to differentiate this syndrome from Alzheimer's disease and thus revived interest in a clinical phenomenon that had been largely forgotten (Mesulam, 1982). The majority of cases reported in the literature have involved English speakers, although there have been reports of a few French-, Standard German-, Japanese-, Italian-, and Dutch-speaking patients as well.

Terminology

Mesulam initially suggested the term "slowly progressive aphasia" to characterize this form of progressive language deterioration. Subsequently, other terminologies have been proposed, including progressive aphasia without dementia, progressive nonfluent aphasia, and progressive language impairment without dementia. Currently, the most widely accepted term appears to be primary progressive aphasia (Mesulam, 2001; Kertesz *et al.*, 1994).

Clinical Features

The earliest cognitive symptoms in patients who are eventually diagnosed with PPA are most commonly related to word-finding difficulties. With progression, loss of fluency often takes place, whereas comprehension remains relatively intact. Although the majority of patients with progressive aphasia evolve into a nonfluent aphasia, a subset may also have fluent aphasia. Patients with PPA typically do not complain of memory changes during the early stages of their illness, although some patients mistakenly think of their inability to retrieve words as loss of memory. The progressive decline in speech fluency is accompanied by a similar deterioration of written language functions, and thus difficulties with spelling are frequently an early feature. Patients with PPA differ from patients with early Alzheimer's disease in that not only do they have insight into the progressive decline in their language functions, but they are also profoundly concerned and disturbed by these changes. In rare cases, the earliest symptoms may be limited to articulatory changes, which over time progress to a marked dysarthria, aphasia, and nonfluency (Selnes *et al.*, 1996; Broussolle *et al.*, 1996; Cohen *et al.*, 1993). In some patients, symptoms may remain limited to language functions for more than 10 years, whereas others progress to a more generalized intellectual decline after 2 to 3 years. Patients with PPA do not have any of the marked personality changes, or difficulties with activities of daily living or self-care, that are commonly seen in other degenerative disorders.

Linguistic and Neuropsychological Features

There may be considerable heterogeneity in the language symptoms of patients with PPA, but a slowly progressive dysnomia is by far the most common presenting symptom (Westbury and Bub, 1997; Jodzio, 1999). Some patients have significant difficulties with word retrieval in their spontaneous speech, but may perform nearly normally on standardized measures of confrontation naming, such as the Boston Naming test (Kaplan *et al.*, 1983). Naming performance is strongly determined by word frequency, and certain classes of words, such as names of flowers, animals, and vegetables, are often most vulnerable during the early stages of the illness. Patients with nonfluent PPA have been shown to have disproportionate difficulties with naming verbs, whereas those with fluent aphasia have more difficulties with nouns (Hillis *et al.*, 2004).

Comprehension of everyday conversational speech is typically well preserved during the first few years after symptom onset, although formal testing will demonstrate mild abnormalities in a significant subset of the patients. Repetition is generally spared for several years, with some studies reporting mild deficits after 8 or 9 years of progression. This suggests that

the underlying disease process does not typically involve white matter tracts during the early stages of the illness. The evolution of reading deficits shows a temporal trend similar to that of the repetition impairment, consistent with the observation that the underlying disease process tends to spare the most posterior cortical regions during the early stages of the illness (Karbe *et al.*, 1993).

The nonlinguistic features of PPA by definition emerge several years after the first language symptoms. Because performance on standardized neuropsychological measures often depends on verbal abilities, it can sometimes be difficult to separate specific neuropsychological deficits from the underlying progressive aphasia. Therefore, nonverbal measures of memory, such as the Warrington Recognition memory test, are preferable to standard verbal list-learning tests of memory. With disease progression, patterns of cognitive abnormalities consistent with executive functioning (attention/working memory; abstraction/cognitive flexibility) are often noted (Zakzanis, 1999).

Differential Diagnosis

Because the earliest symptoms of PPA are so subtle that they are noticeable only to the patient, some patients may be mistakenly thought to have a functional illness when they first approach their physicians. With progression, the language changes can be documented by careful neuropsychological testing. Performance on standard mental status screening tests such as the Mini Mental State Exam, usually remains normal, however. Additionally, normal performance on tests of memory, calculations, visuoconstruction, and executive functions will help differentiate PPA from early Alzheimer's disease. Although most patients with frontotemporal dementia do not have aphasia, subgroups with prominent early speech and language changes are now recognized. Semantic dementia is a form of frontotemporal dementia that presents with progressive loss of semantic knowledge and dysnomia (Snowden *et al.*, 1992). Motor neuron disease may also present with a nonfluent, progressive aphasia, although with a more rapid progression (Catani *et al.*, 2003). The absence of significant personality and behavioral changes may help distinguish patients with PPA from other patients with frontotemporal dementia syndrome. Patients with corticobasal degeneration may occasionally present with an initial aphasia, but subsequent development of unilateral motor symptoms or apraxia will differentiate these patients from those with PPA. Other conditions that may present with an initial isolated, progressive aphasia include Creutzfeldt-Jakob disease (Mandell *et al.*, 1989; Kirk and Ang, 1994). Other focal degenerative disorders with selective involvement of higher cortical functions include slowly progressive pure dysgraphia (Luzzi and Piccirilli, 2003), slowly progressive pure word deafness (Otsuki *et al.*, 1998), progressive prosopagnosia, and slowly progressive apraxia (Otsuki *et al.*, 1997). Although the great majority of reported cases of PPA have been sporadic, a few cases of familial progressive aphasia have been reported. Neuropathological findings in cases of progressive aphasia have been varied and do not typically correspond to any of the classic neuropathological disorders. Most of the reported cases have had diffuse or focal neuronal loss, cortical gliosis, or focal spongiform changes.

Laboratory Testing

Brain imaging with MRI is typically the first step in the evaluation of patients with PPA. This will help exclude neoplasms or other structural causes of cognitive impairment. Routine blood studies to rule out thyroid and parathyroid disease should be performed. Although rare, progressive dysarthria and dysphagia may be associated with hypoparathyroid disease (Cheek *et al.*, 1990). Serum vitamin B12, folate, and methylmalonic acid should also be included in the initial work-up. Detailed language and cognitive testing may help confirm the diagnosis, even relatively early in the disease progression (Gorno-Tempini *et al.*, 2004; Croisile *et al.*, 2003; Kertesz *et al.*, 2003).

Radiological Features

The principal radiologic feature of PPA is an asymmetric focal atrophy in the perisylvian language areas of the dominant hemisphere (Sinnatamby *et al.*, 1996). This pattern of atrophy may not become apparent, however, until the disease has progressed for some time (Figure 1). Positron-emission tomography (PET) studies of PPA have documented a heterogeneous pattern of hypometabolism involving principally the frontal, temporal, and parietal regions of the dominant hemisphere. In approximately one-third of the PET studies reported to date, bilateral abnormalities were found.

Treatment

There are no specific medical treatments currently available that will reverse or slow the progression of the language symptoms, nor are there systematic studies of the efficacy of cholinergic medications in patients with PPA. Medical treatments typically focus

Figure 1 Magnetic resonance imaging scan of a patient with a four-year history of primary progressive aphasia. The scan demonstrates an asymmetrical distribution of atrophy involving the perisylvian areas, with greater atrophy in the left hemisphere (left side of the photograph is the right side of the brain).

on the management of associated symptoms, including depression, anxiety, or agitation. These symptoms may surface during the later stages of the illness. Speech therapy is typically offered during the earlier stages, and treatment focuses on the specific language functions that are impaired. An alternative to speech therapy is the use of augmentative communication devices. These are generally useful as long as the patient's general cognitive skills are reasonably intact. No systematic trials of speech therapy have been reported for patients with PPA.

Prognosis and Complications

At present, there is no known disease-modifying treatment for the degenerative diseases that may be associated with the clinical syndrome of PPA. The long-term prognosis of primary progressive aphasia is variable. Some patients have survived for as long as 14 years, but the average length of survival after diagnosis is considerably shorter.

Primitive Languages

D Gil, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

The concept of 'primitive' language has a checkered history, reflecting not only our increasing understanding of the nature of language, its evolution, and its relation to human culture and cognition but also our changing mores.

Professional linguists, when confronted with the term primitive language, often react in knee-jerk fashion, saying 'There's no such thing.' To appreciate the reason for this reaction, it is necessary to acknowledge the ways in which the notion of primitive language has been subject to abuse.

The ancient Greeks believed that all the peoples surrounding them were barbarians whose languages consisted of mere babbling and grunting. Similar prejudices were entertained by many other civilizations and, indeed, have persisted into the present. A still-widespread belief among laymen today is that the languages of so-called primitive people are themselves primitive, impoverished, and incapable of fulfilling the variegated functions associated with the languages of the great civilizations: English, Chinese, and others. However, increasing familiarity with the world's languages over the past couple of centuries has solidly refuted this belief: we now know that there is no correlation whatsoever between how advanced a civilization is – for example, whether people walk barefoot through the jungle or ride spacecraft to the moon – and how rich and complex its language is. Thus, perusal of any introductory linguistics textbook will reveal bushmen languages of the Kalahari Desert with more than 100 different consonants, languages of the Amazon river basin with four or more different past tenses, depending on remoteness, and aboriginal languages of Australia with words of such structural complexity that they can convey the meaning of a lengthy sentence in English. In this sense of the term, then, there are indeed no primitive languages.

Nevertheless, going beyond such ill-informed notions and abstracting away from the pejorative connotations sometimes associated with the word, the term primitive may still be of relevance to language and linguistics in a number of ways. In general, in other domains the term primitive possesses two related senses. First, it can be used to characterize objects belonging to the distant past – for example, a Paleozoic trilobite or a Paleolithic piece of cave art. Second, for contemporary objects, it can be used to characterize them as resembling their distant-past counterparts – for example, a primitive fish such as the lamprey, or a primitive art school such as Haitian *peinture naïve*. In the latter sense, and in view of the fact that evolution typically involves a unidirectional progression from simplicity to complexity, the term primitive can also be used to characterize a present-day object as being of simpler structure than other objects of similar kind. And indeed, each of these two senses is clearly applicable also within the domains of language and linguistics.

In the former sense, the term primitive language refers to languages spoken in the distant past, either by humans or by our prehuman ancestors. There is broad consensus that 1000 years ago languages were very much the same with regard to their major design features as they are today but that 1 billion years ago our prehuman ancestors did not have language in any significant form. This raises the question of whether somewhere in the immense gap between these two dates there existed languages in some intermediate stage of evolution that might meaningfully be characterized as primitive.

One way to approach this question is to look at how animals communicate. Several species of monkeys have been reported to possess inventories of predator cries. For example, the vervet monkey has

Primitive Languages

D Gil, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

The concept of 'primitive' language has a checkered history, reflecting not only our increasing understanding of the nature of language, its evolution, and its relation to human culture and cognition but also our changing mores.

Professional linguists, when confronted with the term primitive language, often react in knee-jerk fashion, saying 'There's no such thing.' To appreciate the reason for this reaction, it is necessary to acknowledge the ways in which the notion of primitive language has been subject to abuse.

The ancient Greeks believed that all the peoples surrounding them were barbarians whose languages consisted of mere babbling and grunting. Similar prejudices were entertained by many other civilizations and, indeed, have persisted into the present. A still-widespread belief among laymen today is that the languages of so-called primitive people are themselves primitive, impoverished, and incapable of fulfilling the variegated functions associated with the languages of the great civilizations: English, Chinese, and others. However, increasing familiarity with the world's languages over the past couple of centuries has solidly refuted this belief: we now know that there is no correlation whatsoever between how advanced a civilization is – for example, whether people walk barefoot through the jungle or ride spacecraft to the moon – and how rich and complex its language is. Thus, perusal of any introductory linguistics textbook will reveal bushmen languages of the Kalahari Desert with more than 100 different consonants, languages of the Amazon river basin with four or more different past tenses, depending on remoteness, and aboriginal languages of Australia with words of such structural complexity that they can convey the meaning of a lengthy sentence in English. In this sense of the term, then, there are indeed no primitive languages.

Nevertheless, going beyond such ill-informed notions and abstracting away from the pejorative connotations sometimes associated with the word, the term primitive may still be of relevance to language and linguistics in a number of ways. In general, in other domains the term primitive possesses two related senses. First, it can be used to characterize objects belonging to the distant past – for example, a Paleozoic trilobite or a Paleolithic piece of cave art. Second, for contemporary objects, it can be used to characterize them as resembling their distant-past counterparts – for example, a primitive fish such as the lamprey, or a primitive art school such as Haitian *peinture naïve*. In the latter sense, and in view of the fact that evolution typically involves a unidirectional progression from simplicity to complexity, the term primitive can also be used to characterize a present-day object as being of simpler structure than other objects of similar kind. And indeed, each of these two senses is clearly applicable also within the domains of language and linguistics.

In the former sense, the term primitive language refers to languages spoken in the distant past, either by humans or by our prehuman ancestors. There is broad consensus that 1000 years ago languages were very much the same with regard to their major design features as they are today but that 1 billion years ago our prehuman ancestors did not have language in any significant form. This raises the question of whether somewhere in the immense gap between these two dates there existed languages in some intermediate stage of evolution that might meaningfully be characterized as primitive.

One way to approach this question is to look at how animals communicate. Several species of monkeys have been reported to possess inventories of predator cries. For example, the vervet monkey has

one cry for eagles, another for leopards, and yet another for snakes. Thus, such monkeys possess a communicative system containing signs associated with arbitrary meanings, an important design feature of human language. The most parsimonious account for the presence of this particular design feature in several species of monkeys and in humans is to date it back to our common ancestral primate some tens of millions of years ago, who may accordingly be said to have been in possession of a very rudimentary or primitive language consisting of a small set of simple signs.

An important distinction to be made is that between the evolution of actual languages and the evolution of the language capacity: the cognitive ability to entertain the mental representations that underlie actual language usage. Obviously, each individual contemporary language makes use of just part of man's language abilities; it is an open question to what extent the totality of today's 6000 or so languages collectively exhaust these same abilities. It is quite likely that in the past, the linguistic abilities of our prehuman ancestors constituted trailblazers opening up possibilities for actual languages that were only exploited further down the evolutionary path. That linguistic abilities may surpass actual languages is dramatically evidenced by captive apes, such as the bonobo Kanzi and the orangutan Chantek, that have proved capable of acquiring linguistic behavior far beyond that of their counterparts in the wild – for example, the ability to produce and comprehend novel combinations of signs.

An extreme position, one associated with Noam Chomsky and his followers, is that contemporary human linguistic abilities evolved *ex nihilo* in a single, gigantic leap, presumably resulting from a unique genetic mutation. One particular variant of this position associates these abilities with a mutation in the recently discovered FOXP2 gene, sometimes referred to as the 'language gene,' though its functions remain poorly understood. However, even if human linguistic abilities went straight from nothing to what they are today, actual languages probably took a variety of incremental paths over the course of time in order to make use of such abilities, passing through various stages that might meaningfully be characterized as constituting primitive languages.

A somewhat more refined position, one associated with Derek Bickerton, posits a single intermediate stage in the evolution of human linguistic abilities, referred to as protolanguage. Although representative of a past evolutionary stage, protolanguage is also manifest today in a variety of domains, including pidgins, early child language, and language use in extreme conditions. Compared with contemporary human language, protolanguage is characterized by, among other things, the absence of features such as morphological structure, syntactic categories, and syntactic recursion. Clearly, if at some stage the cognitive abilities of our prehuman ancestors were restricted to protolanguage, the actual languages that they spoke, if any, would necessarily have been much simpler than contemporary human languages, and thus worthy of the characterization as primitive.

Another way to understand the past is by working back from the present; however, it is unclear whether such methods can take us back far enough in time to be of relevance to the evolution of language. Classical historical-comparative linguistics is generally assumed to enable the reconstruction of protolanguages dating back at most 5000 to 10 000 years; accordingly, it relies crucially on the assumption of uniformitarianism, whereby the typological characteristics of hypothetical protolanguages must be identical to those of observable contemporary languages. Nevertheless, current work in diachronic linguistics has suggested the existence of a number of processes that have been argued to be unidirectional.

Perhaps the most well-known of these is the process of grammaticalization, whereby content words undergo erosion of form and meaning to become bound grammatical morphemes. On its own, the unidirectionality of grammaticalization would result in a consistent evolutionary path from isolating to inflecting to polysynthetic language types. However, there is plenty of empirical evidence that languages may, in the course of time, lose their morphology and become more isolating, due to various factors, such as phonological attrition, language contact, and others, thereby showing that changes in morphological typology may proceed in either direction.

A more serious, albeit controversial, challenge to the uniformitarian assumption is provided by the observation, due to Talmy Givón, that almost all of the well-documented cases of change in the basic word order of V(erb) and O(bject) involve a shift from OV to VO, not from VO to OV. If indeed this observation withstands the test of further diachronic investigations, then it would seem to imply that at some point in the past, the relative proportion of languages with basic OV word order was significantly higher than the roughly 50% that it is today, perhaps even reaching 100%, which would then make it possible to conclude that basic OV word order was a characteristic feature of primitive languages. At present, however, claims such as these remain very speculative.

As noted earlier in this article, the term primitive language may also be understood in a second sense, as referring to contemporary languages that bear some

kind of resemblance to languages of the distant past. Within the time scale of classical historical-comparative linguistics, there is general agreement that some languages may change faster than others, either in terms of their overall structure or with respect to particular grammatical subsystems. For example, it has been claimed that within the Semitic language family, Arabic is more conservative than Hebrew with respect to its consonantal inventory, whereas Hebrew is more conservative than Arabic with respect to certain aspects of its verbal morphology. Thus, in diachronic linguistics, the notion of conservativity may be viewed as a near-past analogue of the distant-past notion of primitive language.

Potential similarities between contemporary languages and those of the remote past may be sought in the realm of structural simplicity. As a reaction to the misguided belief that primitive people speak primitive languages, an alternative dogma has become prevalent, to the effect that all languages are of equal overall complexity. In order to maintain such equality, languages must be endowed with subtle and intricate compensatory mechanisms guaranteeing that if something is lost somewhere, something else will replace it somewhere else. One oft-cited example of such a trade-off is that in which the loss of a case marking system, for instance in Romance languages, is accompanied by the rise of fixed word order, morphological simplification thus triggering an increase in syntactic complexity. However, typological studies have shown that case marking and fixed word order are not in complementary distribution: languages may in fact have both properties, or neither. In addition, doubt has been cast on the theoretical plausibility that such holistic compensatory mechanisms apply across diverse grammatical domains. More generally, a number of recent studies have called into question the validity of the dogma that all languages are of equal global complexity, suggesting instead that there may in fact exist simpler languages and more complex ones.

If indeed some languages are simpler than others, then this could be because they have retained the simplicity of their distant ancestors or because they have shed the complexity of their more recent ancestors. One possible instance of the latter scenario is Riau Indonesian, which has been argued to be of greater overall simplicity than its hypothesized ancestral language, proto-Austronesian. Yet another potential source of simple languages is provided by the kind of radical restructuring characteristic of pidgins and creoles. Recently, John McWhorter argued that the grammars of creole languages are consistently simpler than those of noncreole languages, since as 'new' languages they have not been around long enough to accrue the kinds of grammatical complexity characteristic of other, 'older' languages. Thus, cases such as these might also merit the appellation of primitive languages, in that by dint of their overall simplicity, they presumably resemble languages of our distant past.

However, in view of its negative connotations and inherent ambiguities, it is probably advisable to eschew the use of the term primitive language in favor of other, more precise and less controversial terms.

Principles and Parameters Framework of Generative Grammar

R Freidin, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

The main task of linguistic theory "must be to develop an account of linguistic universals that, on the one hand, will not be falsified by the actual diversity of languages and, on the other, will be sufficiently rich and explicit to account for the rapidity and uniformity of language learning, and the remarkable complexity and range of the generative grammars that are the product of language learning" (Chomsky, 1965: 27–28). The Principles and Parameters (henceforth P&P) framework of generative grammar attempts to fulfill this goal by postulating a specific set of general mechanisms and principles of grammar that are assumed to be part of the innate knowledge a language learner brings to the task of language acquisition – more precisely, the acquisition of a grammar of a human language. To the extent that much of a speaker's knowledge of his/her language can be derived from this system of mechanisms and principles, the need for language-particular rules of grammar diminishes – thus contributing to an explanation for the rapidity and uniformity of language acquisition. From this perspective, much of the diversity across languages can be viewed as the result of systematic differences in the way the mechanisms and principles apply to the grammars of various languages. These differences appear to fall within a restricted range of options, referred to as parameters. For example, some languages require an overt subject in declarative sentences (e.g., English and French), whereas others allow declarative sentences without overt subjects, presumably where a subject pronoun is deleted (e.g., Spanish and Italian). These options are also assumed to be determined by the language faculty, thus specified as part of Universal Grammar (UG). Within this framework, research on language variation is based on the working hypothesis that much of the apparent diversity among languages can be reduced to instances of parametric variation. This hypothesis has generated a substantial amount of promising research in the area of comparative grammar (see Jaeggli and Safir, 1989; Freidin, 1991, 1992, 1996; Baker, 1995, 2001; Rizzi, 2000).

It is worth noting that modern comparative grammar has a much more ambitious and wide-ranging goal than its 19-century predecessor. Both are concerned with establishing an explanatory basis for the relationships between human languages. The neogrammarians of the 19th century were focused primarily on relationships between languages and groups of languages in terms of common ancestry. Contemporary generative grammar is concerned with a theory of grammar that is postulated to be an innate component of the human mind/brain, a faculty that all humans share as part of their genetic identity and that guides the acquisition of language. Thus the theory of grammar establishes the relationship among all human languages – not only those that happen to be related by historical accident (e.g., common ancestry).

The P&P approach to the study of human language came into focus in the late 1970s and has evolved substantially over the past decade as basic assumptions and proposals have been subjected to a critical re-evaluation within the Minimalist Program (see Chomsky, 1995b; Freidin, 1997; and **Minimalism** in this encyclopedia). Initially, the P&P framework was based on a system of grammatical principles, formulated in terms of fundamental notions of grammatical analysis (e.g., case, agreement, binding, and government). These principles formed the core of modules (e.g., Case and government) that operated within derivations to determine the behavior of syntactic rules, the mechanisms that generate syntactic representations for linguistic expressions. They applied either to derivations (i.e., the application of rules) or to the representations constructed by derivations. Over the past decade, significant parts of this modular theory of grammar have been eliminated under minimalism. The conditions on rule application that remain are for the most part formulated in terms of principles of efficient computation, while conditions on representations have been recast in terms of economy principles that apply at the two external interfaces: Phonetic Form (PF) at the sensorimotor interface and Logical Form (LF) at the conceptual–intensional interface.

The system of grammatical principles initially proposed as the core of P&P evolved out of the study of conditions on the application of transformations, beginning with Chomsky's work on the A-over-A Principle in the early 1960s (see Chomsky, 1964) and continuing with Ross' work on island constraints (Ross, 1967, 1984) and Chomsky's extension of the conditions framework (Chomsky, 1973). One of the first important breakthroughs in modern comparative grammar came from the work of Kayne (1975) and Quicoli (1976a, 1976b), which demonstrated that certain abstract conditions on the application of transformations, postulated for the analysis of English in Chomsky (1973), also applied to some very different constructions in Romance involving clitics and quantifiers. Another crucial step in the development of the current approach was achieved with the

demonstration (Chomsky, 1976) that under Trace Theory the behavior of transformational rules followed from general principles and therefore that transformations could be stated in an optimally general form – essentially as bare elementary transformational operations (e.g., 'substitute α' or 'adjoin α to β'). Transformational rules in such general form could be viewed as rules of UG (the theory of grammar) rather than as language-specific rules of a particular grammar (or as construction specific rules [e.g., a relative clause transformation]).

The study of filters (conditions on representations) provides another major element of the initial framework (see Chomsky and Lasnik, 1977), one which raises important empirical questions regarding the status of various levels of syntactic representation. This line of research led to the realization of the central role of the notions of Case and government for the theory of grammar (due to Jean Roger Vergnaud, see Rouveret and Vergnaud, 1980), and ultimately to Chomsky's (1981) reformulation and extension of the entire theory, commonly referred to as government and binding (or GB) theory.

Chomsky (1981) related phrase structure theory and the theory of transformations in a new way. Up until this version of the theory of generative grammar, the theory of phrase structure and the theory of transformations had developed more or less independently: phrase structure rules and transformations were considered independent grammatical mechanisms, both necessary for constructing syntactic representations. By defining a notion of government in terms of the theory of phrase structure and then establishing the major role it plays in the various conditions that determine the behavior of transformations, Chomsky identified a conceptual thread that links the two theories.

During the past decade under the minimalist program, the connection between phrase structure and transformations has been reconstructed so that it is only transformations that construct syntactic representations. The new bare phrase structure theory (see Chomsky, 1995a) radically revises the notion of syntactic derivation in a way that significantly affects the organization and function of grammar under the P&P framework.

The remainder of this article sketches some of the essential parts of the current P&P framework. For an account of the preminimalist version of this framework, see Freidin (1994a).

Mechanisms for Phrase Structure Representations

Under the current P&P framework, syntactic (i.e., phrase structure) representations are constructed by a single transformational operation Merge, an adjunction operation that concatenates two syntactic objects and labels the resulting syntactic object with the syntactic category features of one of the two elements concatenated. Syntactic derivations begin with an array of lexical items selected from the lexicon, a numeration N. Merge then operates on N, constructing a phrase marker containing all the elements in N. In a derivation, lexical insertion results when Merge applies to a lexical item in N. Thus, when Merge applies to a preposition *from* and a NP *my sons* (itself constructed from the merger of two lexical elements), the result is a PP *from my sons* containing a P and a NP as constituents, where *from*, the head of the construction, projects its syntactic category P to label the new construct. The operation is constrained by an Inclusiveness Condition (1), which radically restricts the kind of syntactic objects that can be created in a derivation.

(1) Inclusiveness Condition: any structure formed by the computation (in particular, PF and LF) is constituted of elements already present in the lexical items selected for N; no new objects are added in the course of computation apart from rearrangements of lexical properties. (Chomsky, 1995b: 228)

Condition (1) prohibits the categorial distinction of levels of phrasal projection and the use of indices. Merge is further constrained under the assumption that it is a strictly binary operation and therefore there can only be two immediate constituents of any phrasal category, never more and never less.

Given Merge, every phrase in a phrase structure representation has a unique head, the element that projects its syntactic category features as the label of the phrase. The application of Merge is further constrained by the order in which a head is merged with other constituents. A complement (generally an argument of the head when the head is some form of predicate [e.g., verb, adjective, or derived nominal]) is always concatenated with the head before other kinds of constituents. A specifier is always concatenated with the phrasal projection of the head last and therefore is always an immediate constituent of a maximal phrasal projection. Adjuncts (generally modifiers) are concatenated with a head (when there are no complements) or a phrasal projection of the head after complements and before the specifier.

The application of Merge that concatenates two independent syntactic objects (lexical items from the lexicon or phrases constructed from the concatenation of lexical items) is called External Merge (EM), in contrast to the application of Merge that applies to a single syntactic phrase by adjoining a subphrase of it to the phrase itself (i.e., to its root). This latter

application of Merge, which is called Internal Merge (IM), performs movement operations as in the case of simple passive sentences.

(2) Seymour was arrested in Shanghai.

Because the subject NP *Seymour* is interpreted at LF as the object of *arrested*, it is first merged (via EM) as the object of the verb and then moved (via IM) to subject position where it is pronounced (at PF). At LF, the syntactic representation of (1) contains a copy of subject in object position.

(3) Seymour_i was [$_{VP}$ arrested Seymour_i in Shanghai]

(Although indices are prohibited under the Inclusiveness Condition [1], copies here are indicated here via coindexing as a notational convenience.) IM adjoins a copy of the object to the Tense Phrase (TP) *was arrested Seymour in Shanghai* and projects the label T, thereby creating the specifier position of TP.

IM involves only the adjunction operation, i.e. only a single elementary transformational operation. The deletion operation applies to unpronounced copies of syntactic elements only at PF (see Nunes, 2004 for a detailed discussion). It follows that grammatical transformations do not compound elementary operations (Chomsky, 1980). A syntactic element and its copies form a nontrivial chain. The elements of a chain are distinguished in terms of their contexts (e.g., in [2] where the object *Seymour* is a sister of a verb while the subject *Seymour* is a sister of a TP (*was arrested Seymour in Shanghai*).

In addition to the movement of NP to the Spec-TP position in passive constructions, IM also displaces the finite auxiliary verb in yes/no questions (4) and direct questions involving an interrogative pronoun (5), as well as wh-phrases in direct and indirect questions.

(4) Was Seymour arrested in Shanghai?

(5) In which city was Seymour arrested?

Example (5) involves three kinds of movement: (a) of an NP (*Seymour*), (b) of a head (*was*), and (c) of a wh-phrase (*in which city*). Each is performed by the same operation IM.

Given that IM is restricted to adjoining a phrase to the root, derivations cannot segregate applications of IM from those of EM, as was done in earlier versions of transformational grammar where movement transformations applied after the construction of an initial phrase marker. Thus in (3), the movement of the NP *Seymour* via IM occurs before the insertion of the complementizer *that* (the head of the Complementizer Phrase [CP]), as well as the verb *believe* and the pronoun *they*, via EM.

(6) They believe [$_{CP}$ that [$_{TP}$ Seymour_i was arrested Seymour_i in Shanghai]]

Because of this, derivations under bare phrase structure theory cannot define a canonical level of D-structure as in previous theories. Therefore, there is no level of D-structure under this theory.

Restricting the application of Merge to the root yields a version of 'strict cyclicity' (Chomsky, 1973; Freidin, 1978, 1999; H. Lasnik, personal communication, 2004), where a phrase that has become a constituent of another phrase cannot be altered by further applications of Merge (either EM or IM).

Constraints on Derivations and Representations

The operation Merge sketched in the previous section will by itself generate deviant constructions and therefore must be supplemented by further constraints to distinguish deviant from nondeviant utterances in a language. As has been demonstrated in research on dozens of languages over the past several decades, these constraints apply generally across languages. Constraints have been formulated in one of two ways, as conditions on the application of rules (i.e., on derivations) or as conditions on the representations constructed by rules. In current work, both kinds of constraints have been formulated in terms of a notion of computational economy whereby the operation of rules and the representations they generate are optimally efficient in computing the relation between sound and meaning in linguistic expressions. In essence, economy conditions prohibit superfluous steps in derivations and superfluous elements in representations.

Full Interpretation

The fundamental condition on representations, Full Interpretation (FI) (Chomsky, 1986), requires that all elements in the representations at the interface levels, PF and LF, must be fully interpretable. Thus at LF, representations must contain no phonetic material under the assumption that such material cannot be interpreted by the cognitive modules that interface with LF. Similarly, PF representations must not contain any semantic information or syntactic constructs such as nontrivial chains, which cannot be interpreted at the sensorimotor interface.

Given FI, a derivation from N to LF must contain a point where phonetic material is separated from the syntactic representation and transferred to the phonological component of the grammar that constructs PF representations. This point, called Spell-Out, roughly corresponds to S-structure in previous analyses if there is only one point in a derivation. However, if there is multiple Spell-Out (Uriagereka, 1999; Chomsky, 2001), then classical S-structure cannot be constructed.

Applied at LF, FI eliminates constructions with superfluous arguments. For example, Merge could construct the following deviant example (7) in addition to the nondeviant examples (8a, 8b).

(7) *John gave Bill a book to Mary.

(8a) John gave Bill a book.
(8b) John gave a book to Mary.

The verb *gave* will assign argument functions (θ-roles) to the three NPs in both (8a) and (8b), but only three of the four NPs in (7). It can assign the indirect object θ-role to either *Bill* or *Mary*, but not to both. Therefore one of these NPs will not have a θ-role at LF, in violation of FI.

Case phenomena in languages are also governed by FI under the assumption that Case features are superfluous (hence uninterpretable) at both LF and PF and therefore have to be eliminated in the course of the derivation from N to LF. This can be illustrated with the following paradigm.

(9a) It is likely that he will graduate in June.
(9b) He is likely to graduate in June.
(9c) *It is likely he/him to graduate in June.

In (9a), the nominative Case pronoun *he* is the subject of the verb *graduate* and the matrix subject is the pleonastic element nonreferential *it*, which has no θ-role. The predicate adjective *likely* is a one-place predicate that assigns its single θ-role to the clausal complement *that he will graduate in June*. In (9b) the clausal complement of *likely* is infinitival rather than finite and the NP that is interpreted as the subject of the infinitival clause (*he*) has moved via IM to the subject position of the main clause. This movement is from a position that is assigned a θ-role to one that is not. This movement is obligatory because when it does not occur, as in (9c), the result is deviant. The difference between (9a, 9b) and (9c) is that the pronouns in the former occur in a position where they are licensed, whereas neither pronoun in the latter is licensed in that position. Once a Case feature is licensed it can be eliminated from the derivation and therefore will not show up at LF or PF. If it is not licensed, then it shows up at LF and PF in violation of FI. This analysis generalizes to overt NPs that do not show overt morphological Case (e.g., substitute the name *Adam* for the pronouns in [9] and the same result obtains), and therefore concerns a notion of abstract structural Case, which plausibly plays no role at PF (in contrast to overt morphological Case).

This analysis generalizes to the analysis of simple passives as discussed above. Thus compare (2) with the deviant (10).

(10) *It was arrested Seymour in Shanghai.

The pleonastic nonreferential *it* occurs in a non-θ-position and is licensed for Case as the subject of a finite clause. In contrast, *Seymour* occurs in a θ-position. Assuming that the reason the NP *Seymour* moves in (2) is to get to a Case-licensed position and thereby eliminate its Case feature, then the object position of a passive predicate must not be licensed for Case, in which case the NP *Seymour* violates FI at LF and PF because it still has whatever abstract Case feature it brings from the lexicon.

The abstract structural character of Case licensing can be more sharply illustrated in languages with more complex Case phenomena than English. Consider the following paradigm from Icelandic.

(11a)	Jóni	batnaði	veikin		
	John-DAT	recovered-from	the-disease-NOM		
(11b)	Ég	tel [$_{TP}$	Jóni	hafa	batnað	veikin]
	I	believe	John-DAT	to have	recovered-from	the-disease-NOM
(11c)	[$_{CP}$ að [$_{TP}$	PRO	batna		
		PRO-DAT	to-recover-from		
		veikin]]	er venjulegt		
		the-disease-NOM	is usual		
(11d)	*[$_{CP}$ að [$_{TP}$	Jóni	batna		
		John-DAT	to-recover-from		
		veikin]]	er mikilvægt		
		the-disease-NOM	is important		

Although the verb *batna* ('recover from') selects a dative subject as a lexical property, (11c) illustrates that the null subject PRO can satisfy this requirement even though it has no phonetic content. Yet as (11d) shows, lexical satisfaction of the Case requirement is not sufficient since the lexically Case-marked NP cannot have phonetic content. The subject of the infinitive in (11d) is not structurally licensed for Case, in contrast to (11b) where the dative NP occurs in an 'exceptional Case-marking' context governed by the matrix verb *tel*. In (11b), the element that determines the actual morphological Case is distinct from the element that licenses abstract Case. Such examples demonstrate the need to distinguish morphological Case assignment from abstract structural Case licensing (see Freidin and Sprouse, 1991). Both requirements must be satisfied in order to remove uninterpretable Case features from the derivation.

The FI account of obligatory movement can be extended to wh-movement (i.e., movement to Spec-CP position) under the assumption that the head C contains a formal syntactic feature, which is uninterpretable and therefore must be eliminated in the course of the derivation. In (12), for example, the wh-phrase moves from a Case-marked object position to Spec-CP, which is Case-less.

(12a) Which books did you borrow?
(12b) [$_{CP}$ [$_{NP}$ Which books]$_i$ did$_j$ [$_{TP}$ you did$_j$ borrow [$_{NP}$ which books]$_i$]]

It is also a movement from a θ-position to a non-θ-position. Since the movement must be overt (i.e., show up in PF), the formal feature involved must be uninterpretable at both LF and PF and therefore must be eliminated before Spell-Out.

In some languages (e.g., Chinese), wh-phrases do not move in overt syntax. Instead they move after Spell-Out i.e. covertly in LF (see Huang, 1981/1982). The covert movement of wh-phrases is also motivated by FI under the assumption that a wh-phrase constitutes a quasi-quantifier and as such must bind a variable created by movement at LF. Otherwise the quantifier without a variable to bind, a case of vacuous quantification, is uninterpretable. Presumably, Chinese lacks the formal feature that forces overt wh-movement.

Agreement features on verbs are also formal syntactic features that are considered uninterpretable at PF and LF and therefore can trigger a violation of FI unless they are eliminated before Spell-Out. If the agreement features on finite T enter the derivation unvalued and are then valued by the agreement features of the head of Spec-TP, then unless an NP is merged in that position, the agreement features of T remain unvalued and violate FI at the interfaces. Thus it follows from FI that a finite clause must have a syntactic subject, even in languages where the subject is absent at PF. Thus agreement features on verbs can also be considered as a trigger for NP-movement.

Whether this analysis can be extended to cases of improper movement as in (13) is not as clear.

(13a) *He is likely will graduate in June.
(13b) *[$_{TP}$ he$_i$ is likely [$_{TP}$ he$_i$ will graduate in June]]

When the pronoun *he* is first merged in the complement clause, it values the agreement features of the complement T. It is generally assumed that once a NP values the agreement features of one T, it cannot value the agreement features of another. Assume this to hold whether or not the NP is frozen in place after agreement applies. Then the agreement features on matrix T in (13) will remain unvalued, in violation of FI.

Not all improper movement cases involve a violation of FI. In (14), movement is from the subject of a finite clause to the subject of an infinitival clause.

(14a) *It is easy he to believe has written a book.
(14b) *it is easy [$_{TP}$ he$_i$ to believe [$_{TP}$ he$_i$ has written a book]]

The pronoun *he* moves from a Case-marked to a Case-less position. The Case features of the pronoun and the agreement features of the finite T are all eliminated from the derivation, so the result does not violate FI. However, notice that the uninterpretable Case and agreement features were eliminated prior to the movement of the pronoun.

One way to account for the deviance of (14) is to prohibit movements between two θ-positions by restricting the number of θ-roles a chain may have to one (see Freidin, 1978; Chomsky, 1981). An alternative is to prohibit the movement itself on the grounds that it is unmotivated by any grammatical factor, in contrast to legitimate phrasal movements. Since the pronoun *he* is both licensed for Case and assigned a θ-role in its initial position as subject of the complement of *believe*, there is no motivation for it to move further. From this perspective, movement is viewed as a 'last resort' to save a derivation from violating FI. Any movement that fails to meet this criterion is superfluous and therefore ruled out on general grounds of computational efficiency.

Locality of Movement

In addition to constraints on when and where a phrase must move and when it may not move, must also specify 'how far' a movement can be. Although IM has the capability of moving a constituent indefinitely far away from its EM position, actual movement phenomena in languages demonstrate that certain syntactic boundaries may not be crossed; in effect, IM may not move a constituent 'too far' away. Thus movement operations are bounded within a particular syntactic domain. Compare, for example, the long-distance wh-movement in (9a), where the wh-phrase is interpreted as the verbal object in a clause (analyzed here as a Tense phrase (TP) contained in a Complementizer phrase [CP]) that is itself embedded in three other clauses, to the much shorter but impossible movements in (15b) and (15c).

(15a) [$_{CP}$ who$_i$ did [$_{TP}$ you say [$_{CP}$ that [$_{TP}$ Mary knows [$_{CP}$ that [$_{TP}$ Bill told Sam [$_{CP}$ that [$_{TP}$ Rachel admires who$_i$]]]]]]]]
(15b) *[$_{CP}$ who(m)$_i$ did [$_{TP}$ [$_{NP}$ your interest in who(m)$_i$] surprise Mary]]
(15c) *[$_{CP}$ what$_j$ did [$_{TP}$ John wonder [$_{CP}$ [$_{PP}$ to whom]$_i$ [$_{TP}$ Bill gave what$_j$ [$_{PP}$ to whom]$_i$]]]]

In contrast to (15a), the movement in (15b) is intraclausal rather than interclausal and the movement in (15c) only crosses one clause boundary instead of many.

The boundedness of IM can be accounted for in terms of a general principle of grammar that designates certain categories as bounding categories and

sets a limit for bounding categories that may be crossed in a single-movement operation. This limit is fixed in UG at one bounding category. Two syntactic positions are said to be subjacent to one another if they are separated by no more than one bounding category. The principle for bounding, the Subjacency Condition, has the effect of prohibiting a single movement that crosses more than one bounding category.

(16) Subjacency Condition
Movement can only be to a subjacent position.

This principle can be formulated as a condition on chain links, in which case it constitutes a condition on representations rather than a condition on the application of rules (see Freidin, 1978; Browning, 1991). Alternatively, it has been argued that the Subjacency Condition must be formulated as a condition on the application of the movement rule (see Lasnik and Saito, 1984, 1992). Assuming the bounding categories for Subjacency are NP and TP, (16) rules out (15b) and (15c). To account for (15a), it is assumed that wh-movement operates locally when it can, so that *who* moves successively through each of the intervening Spec-CP positions, thereby avoiding a Subjacency violation. The condition applies more generally to many other constructions involving movements across two NPs or across two TPs (see Freidin, 1992 for discussion and references). As a condition on representations, it applies at S-structure (see Freidin and Lasnik, 1981 for discussion) and therefore is incompatible with the multiple Spell-Out analysis mentioned above.

Bounding effects appear to vary across grammars. In some idiolects of Italian, it is possible to extract a relative pronoun out of an indirect question (see Rizzi, 1982).

(17) il mio primo libro, $[_{CP}$ che$_i$ $[_{TP}$ credo $[_{CP}$ che$_i$ che $[_{TP}$ tu sappia $[_{CP}$ $[_{PP}$ a chi$]_j$ $[_{TP}$ ho dedicato che$_i$ $[_{PP}$ a chi$_j]]]]]]]$ me è sempre stato molto caro
'my first book, which I believe that you know to whom I dedicated, has always been very dear to me'

The sentence is well formed even though the movement between two trace positions crosses two TPs. This suggests that TP is not a bounding category in this idiolect of Italian. Nonetheless, a bounding effect occurs in Italian when a single movement of *che* crosses two CPs, as in (18).

(18) *il mio primo libro, $[_{CP}$ che$_i$ $[_{TP}$ so $[_{CP}$ $[_{PP}$ a chi$]_j$ $[_{TP}$ credi $[_{CP}$ che$_i$ che $[_{TP}$ abbia dedicato che$_i$ $[_{PP}$ a chi$_j]]]]]]]$ me è sempre stato molto caro
'my first book, which I know to whom you believe that I dedicated, has always been very dear to me'

If CP is taken as a bounding category for this idiolect of Italian, then the second and final movement of the relative pronoun *che* violates Subjacency. Similar phenomena pointing to the same conclusion can be found in French and Spanish (see Sportiche, 1981 and Torrego, 1984). Thus the choice of TP vs. CP as a bounding category for Subjacency constitutes one parameter of UG. If both TP and CP are chosen as bounding categories, then Subjacency would prohibit interclausal *wh*-movement. Some languages (e.g., Russian) prohibit this kind of *wh*-movement, a fact that would follow from bounding theory if both TP and CP were bounding categories for Subjacency in these languages.

The Subjacency analysis remains the most general and perhaps the clearest account of syntactic island phenomena (i.e., construction from which the movement of constituents is prohibited). However, it may well be that the Subjacency Condition constitutes a false generalization, as have several other important proposals in the history of generative grammar. Moreover, the stipulation of bounding categories is essentially descriptive rather than explanatory and the principle itself is not easily interpreted in term of economy.

More recently, other analyses have been proposed that cover some of the empirical range of the Subjacency Condition. Chomsky (1993) proposes an economy principle that derivations involve the shortest steps (the Minimal Link Condition; see also Chomsky, 1995b), which prohibits (15c) on the grounds that the movement of *what* to the matrix Spec-CP is not the shortest movement possible because the movement from Spec-CP to Spec-CP is shorter. Chomsky (2001) proposes that subparts of derivations (phases) become inaccessible to further computation because they are transferred to PF and LF when complete. Details aside, under this proposal, *what* in (15c) would be inaccessible for movement because it is not at the edge of the CP phase. The proposals are problematic given that the movements they prohibit for English appear to be possible in several Romance languages (e.g., as in [17] above). Whether there is an alternative to the Subjacency analysis of locality with the same empirical coverage remains to be determined.

Binding Theory

Movement is not the only process that creates relations between pairs of positions within a sentence. Anaphoric expressions also create such relations via the interpretive link to their antecedent. Languages contain two types of anaphoric expressions: those that require the presence of an antecedent in the

same sentence, called bound anaphors (i.e., reflexive pronouns and reciprocal expressions, henceforth anaphors), and pronouns (including anaphoric epithets like *the bastard*), which can occur in a sentence without an antecedent. Binding theory is concerned in part with the conditions under which anaphors and pronouns can be linked to an antecedent. (For more detailed discussion see Freidin, 1986; Lasnik, 1989; Koster and Reuland, 1992; and Chomsky and Lasnik, 1993.)

Bound Anaphors Formally, an antecedent binds an anaphoric expression when the anaphor is a constituent of the phrase that is merged with the antecedent (i.e., its sister). The paradigm for anaphors in (19) illustrates that all possible binding relations are not licit. (Again coindexing is used here and in what follows as a notational convenience.)

(19a) simple sentence
we$_i$ help each other$_i$
(19b) finite clause complement:
(19b.i) *we$_i$ expect [$_{CP}$ (that) [$_{TP}$ each other$_i$ will win]]
(19b.ii) *we$_i$ expect [$_{CP}$ (that) [$_{TP}$ Mary will help each other$_i$]]
(19c) infinitival complement:
(19c.i) we$_i$ expect [$_{TP}$ each other$_i$ to help Mary]
(19c.ii) *we$_i$ expect [$_{TP}$ Mary to help each other$_i$]

While all the anaphors in (19) are bound, only those in (19a) and (19c.i) are properly bound. Proper binding of anaphors falls under a principle of grammar, referred to as Principle A of the binding theory, which is given schematically in (20).

(20) Principle A: an anaphor must be antecedent-bound in a local domain δ.

(20) constitutes a principle of UG which, by specifying the local domain δ, is instantiated in the grammar of a particular language as binding condition A.

The local domain for anaphors in English is the domain of an accessible SUBJECT, where SUBJECT stands for a syntactic subject or the agreement element associated with the head of finite TP (given that specifier-head agreement between a syntactic subject and the head T is mandatory in finite clauses). Any syntactic subject is accessible to an anaphor if it binds the anaphor. Thus (19a) and (19c.i) satisfy Condition A because the only accessible subject in each example is the main clause subject to which the anaphor is bound. In (19b.ii) and (19c.ii), the complement subject is accessible to the anaphor, but the anaphor is antecedent-free (i.e., not bound by an antecedent) in the domain of this 'subject'. Therefore, these examples violate Condition A. In (19b.i), the agreement element of the sentential complement constitutes an accessible SUBJECT and in that domain the anaphor is antecedent-free in violation of Condition A. (The precise formulation of the local domain δ for English is somewhat more intricate; see Chomsky, 1986; Freidin, 1986, 1992 for details.)

Cross-linguistically, we find some variation in the local domain *δ* for Condition A. In Korean, for example, the binding domain for reciprocals is that of any c-commanding NP. Thus within a single clause, a direct object may create a binding domain for the object of a PP in VP, as illustrated in (21) (from Hong, 1985).

(21) kitil-i [$_{NP}$ John-kwa Mary]-lil
they-NOM John and Mary-ACC
sero-eke sogehetta
each other-to introduced
they$_i$ introduced [$_{NP}$ John and Mary]$_j$ to each other$_{\{*i,j\}}$

In the corresponding English example, either the subject or the direct object may be the antecedent of the reciprocal. Hence the binding domain for reciprocals in Korean is more restricted than that of English. This indicates that the binding domain for Principle A is subject to parameterization. (See Freidin, 1992: Chap. 7 for a more detailed discussion of parameterized binding.)

Pronouns In contrast to bound anaphors, which must be antecedent-bound within a certain domain, pronouns cannot be bound within certain domains. The paradigm for pronoun binding corresponding to (19), given in (22), illustrates a complementarity between bound anaphors and bound pronouns where a bound anaphor can occur, a bound pronoun may not.

(22a) simple sentence
*the politician$_i$ voted for him$_i$
(22b) finite clause complement:
(22b.i) Clara$_i$ expects [$_{CP}$ (that) [$_{TP}$ she$_i$ will win]]
(22b.ii) Clara$_i$ expects [$_{CP}$ (that) [$_{TP}$ Sam will help her$_i$]]
(22c) infinitival complement:
(22c.i) *Clara$_i$ expects [$_{TP}$ her$_i$ to help Sam]
(22c.ii) Clara$_i$ expects [$_{TP}$ Sam to help her$_i$]

Thus pronoun binding is accounted for by a principle of grammar complementary to Principle A, referred to as Principle B of the binding theory.

(23) Principle B: a pronoun must be antecedent-free in local domain δ.

As with Principle A, Principle B is instantiated in the grammar of a particular language as binding condition B by specifying the local domain δ. As with anaphor binding, this domain varies across

languages. For example, pronoun binding in the Icelandic sentence corresponding to (22c.ii) is not possible.

Given the complementarity of anaphors and bound pronouns illustrated in (19) and (22), it would appear that the specification of the local domain for pronoun binding is identical to that of anaphor binding. Although this complementarity holds for binding within TP and across TP boundaries, it collapses with respect to binding across NP boundaries, as examples (24–25) illustrate.

(24a) they$_i$ never discuss [$_{NP}$ each other's$_i$ work]
(24b) they$_i$ never discuss [$_{NP}$ their$_i$ work]

(25a) every man$_i$ heard [$_{NP}$ a story about himself$_i$]
(25b) every man$_i$ heard [$_{NP}$ a story about him$_i$]

These examples show that the domain statement for Condition B in English cannot be identical to that of Condition A, since if it were, then (24b) and (25b) should be unacceptable on a par with (22a) and (22c.i), contrary to fact.

These examples show that NP constitutes a binding domain for pronouns and the paradigm in (22) shows that TP constitutes another binding domain with one exception – (22c.i) – where the matrix verb governs the complement subject across TP. One property that NP and TP share in common is that they both constitute domains in which predicates (e.g., verbs and derived nominals) may discharge their θ-roles (θ-domains, or complete functional constructs [in the terminology of Chomsky, 1986]). Example (22c.i) shows that the binding domain for pronouns is not the minimal θ-domain containing the pronoun, but rather the minimal θ-domain of the matrix verb, which is implicated in Case licensing of the pronoun. (For further discussion of the representation and interpretation of pronoun binding, see Lasnik, 1989.)

Universally, a pronoun cannot be anaphoric on an antecedent when it is in a structural binding relation to the antecedent (i.e., it is merged with a phrase that contains the antecedent), as in (26).

(26) *she$_i$ expects [$_{CP}$ (that) [$_{TP}$ Sam will help Clara$_i$]]

Example (26) can never be interpreted as a sentence about two people. Note that this is not a matter of the pronoun preceding its antecedent since (27) has the same linear property but not the same interpretive restriction.

(27) His professor praised John in class.

Example (27) can be interpreted as a sentence about two people as well as a sentence about three. The constraint that accounts for the impossibility of the interpretation represented in (26) is designated in the literature as Principle C.

Conclusion

The material covered in this article is merely a sketch of some of the central topics being investigated within the principles and parameters framework. Ongoing research extends the empirical coverage of various subtheories, including parametric variation across languages. Current work also explores a number of promising alternative analyses for various parts of the theory. As in any area of rational inquiry, no assumption is immune to critical inquiry.

For further discussion of these and other topics within this approach to generative grammar, see van Riemsdijk and Williams, 1986; Lasnik and Uriagereka, 1988, 2005; Lasnik, 1999, 2003; Freidin, 1992; Epstein and Hornstein, 1999; and Epstein and Seely, 2002 among many others. Many of the topics under investigation have a long and rich history in generative grammar of the past half century: see Newmeyer, 1986; Freidin, 1994b for an historical account.

The principles and parameters framework of generative grammar attempts to establish the common biological basis for all the world's languages. The current work in comparative grammar illuminates the human language faculty as an intricate computational structure of the human mind that is unique to the genetic endowment of our species. In this way work in contemporary comparative grammar continues to make a major contribution to the emerging cognitive science enterprise.

Principles and Rules

L Mao, Miami University, Oxford, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

The concept of 'rule' and 'principle' is perhaps as venerable as the study of language practices. The view that one particular variety of language is inherently more valuable contributes to the formation of prescriptive rules in relation to grammar, vocabulary, and pronunciation. The 18th century witnessed the need to standardize, to codify English, whose uniformity was promoted in the interest of the newly created union (Crowley, 1996) and whose imposition throughout the British Isles became part of what Leith (1997: 151) calls "internal colonization". On the other hand, China at the turn of the 20th century experienced the need to break loose from the rules and conventions of classical Chinese as it tried to vernacularize its language as part of its modernization effort to create a new language of modernity and progress (Gunn, 1991).

In contemporary linguistics the term 'rule' assumes a new meaning, one that should not be confused with prescriptive rules. According to Noam Chomsky (1957), the rules of language are syntactic and generative, because language is both rule governed and predictable. Chomsky further distinguished the rules of grammar from principles of grammar – the latter do not generate sentences, but act as a set of tests that a sentence must pass to be part of a given language (1986).

However, meaning often defies both predictability and testability, especially when it becomes extralinguistic, and when well-formedness transcends syntax. Instead of focusing on rules of grammar, be they prescriptive or generative, language philosophers and pragmatists focus on "the total speech act in the total speech situation" (Austin, 1962: 149), on rules that either regulate (preexisting) language behavior or create or define new forms of language behavior (Searle, 1969), and on pragmatic principles that can account for the use of language as determined by societal conditions (Mey, 2001). For example, Grice (1975, 1989) developed the cooperative principle, whereby anyone who has a rational interest in participating in talk exchange is expected to be cooperative, to make his or her contribution as required. The cooperative principle, which for Grice is assumed to be in force all the time, and which has been faulted because it elides interpersonal, intercultural power dynamics, subsumes the conversational maxims of quantity, quality, relation, and manner (Grice, 1989: 26). What has to be underscored is that we comply with the maxims as much by flouting them as by honoring them – hence we can mean more than or other than what we say.

Brown and Levinson (1987) turned their attention to politeness principles, proposing that there is a public-self image that we all want to claim and protect – one that consists of the want to be stroked (positive face) and the want to be left alone (negative face). These two competing wants and their concomitant claims for universality have spawned a large body of work on politeness pragmatics. Leech (1983) offered his own principle of politeness, which is predicated upon the notions of cost and benefit, and directness versus indirectness; he further offered a number of subprinciples to account for stylistic aspects of expression. And like Horn (1984), who tried to reduce Grice's conversational maxims, Sperber and Wilson (1995) contended that what is only required for the hearer to work out the speaker's intended message is the principle of relevance, because we humans turn our attention to what seems most relevant to us automatically.

While the formulation of pragmatic principles has greatly extended the scope of linguistics, pragmatic principles themselves do not equip language users with the means to reflect upon the conditions under which they use, or fail to use, language. Metapragmatic principles seek to promote metadiscursive awareness and to account for those underlying forces that, be they local or crosscultural, motivate or constitute particular pragmatic principles (Mey, 2001). This kind of self-reflectiveness becomes central to cultivating critical language awareness, to facilitating an emancipatory use of language (Fairclough, 1989), and to forever asking ourselves: "Whose language are we using?" (Mey, 1985).

Printing and Typewriting

R Bringhurst, Heriot Bay, BC, Canada

© 2006 Elsevier Ltd. All rights reserved.

Mammals, amphibians, reptiles, and birds have been leaving their marks in the soft earth for several hundred million years. In the broadest sense of the word, that is printing. For purposes of this article, however, printing is narrowly defined as the physical replication of written language through prefabricated masters. The earliest known examples of printing in this sense are the imprints of stone seals bearing short inscriptions, usually with accompanying illustrations. These survive in substantial numbers from Mesopotamia, Egypt, and the Indus Valley, and some are close to 5000 years old. (The oldest known Chinese seals are more recent.) The printing of extended texts did not apparently occur until the invention of paper, in Hàn dynasty China (1st century B.C.).

Almost as soon as it was available, paper was used in making rubbings from stone inscriptions. In China between the 1st and 9th centuries A.D., a number of lengthy philosophical and literary texts appear to have been engraved on stone at government expense expressly for this purpose. (This is in marked contrast to the widespread custom of engraving governmental and military proclamations: a class of texts that have seldom, if ever, been copied by the populace for independent study.)

During the Táng dynasty (618–907 A.D.) and possibly somewhat earlier, extended texts, with and without illustrations, were also carved in relief on slabs of wood to serve as printing plates, and the prints were made, again, by rubbing. The method was used to print calendars, charms, and paper money, as well as books. The earliest substantial and dependably dated example known at present is a copy of Kumarajiva's Chinese translation of the Diamond Sutra, printed from seven large wooden plates in the year 868.

Making rubbings from hand-carved wooden plates – xylography, as it is called – remained the primary method of printing in China through the end of the 19th century. To this day, a printing plate or form (that is, a set of pages ready for the press) is known in Chinese as **bǎn** (板 or 版), meaning board or plank, and the most popular fonts of type for many literary purposes are still **sòngtǐ** (宋体): squarish characters based on the woodcut glyphs of the Sòng and later dynasties, rather than **kǎitǐ** (楷体), or characters based directly on the action of the Chinese brush (**Figure 1**).

If a text is carved in a slab of wood and the slab is sawn up into sections, each bearing a single character, you have what is known as movable type: individual glyphs in material form that can be endlessly rearranged into different texts. **Huóbǎn** (活板), the Chinese term for movable type, does in fact mean 'flowing plank' or 'living plank.' In all but its most cursive forms, Chinese script is admirably suited to this concept, because every character is conceived as occupying the same rectangular space. Every piece of type in a Chinese font can therefore be exactly the same size and mechanically interchangeable with every other. The difficulty is that the number of characters required to set any lengthy Chinese text is very large. Even the most rudimentary font needs 5000 to 6000 characters. More serious fonts run from 20 000 to 60 000. That hurdle notwithstanding, movable type was invented in China toward the middle of the Sòng dynasty (around the year 1040) and has never

Printing and Typewriting

R Bringhurst, Heriot Bay, BC, Canada

© 2006 Elsevier Ltd. All rights reserved.

Mammals, amphibians, reptiles, and birds have been leaving their marks in the soft earth for several hundred million years. In the broadest sense of the word, that is printing. For purposes of this article, however, printing is narrowly defined as the physical replication of written language through prefabricated masters. The earliest known examples of printing in this sense are the imprints of stone seals bearing short inscriptions, usually with accompanying illustrations. These survive in substantial numbers from Mesopotamia, Egypt, and the Indus Valley, and some are close to 5000 years old. (The oldest known Chinese seals are more recent.) The printing of extended texts did not apparently occur until the invention of paper, in Hàn dynasty China (1st century B.C.).

Almost as soon as it was available, paper was used in making rubbings from stone inscriptions. In China between the 1st and 9th centuries A.D., a number of lengthy philosophical and literary texts appear to have been engraved on stone at government expense expressly for this purpose. (This is in marked contrast to the widespread custom of engraving governmental and military proclamations: a class of texts that have seldom, if ever, been copied by the populace for independent study.)

During the Táng dynasty (618–907 A.D.) and possibly somewhat earlier, extended texts, with and without illustrations, were also carved in relief on slabs of wood to serve as printing plates, and the prints were made, again, by rubbing. The method was used to print calendars, charms, and paper money, as well as books. The earliest substantial and dependably dated example known at present is a copy of Kumarajiva's Chinese translation of the Diamond Sutra, printed from seven large wooden plates in the year 868.

Making rubbings from hand-carved wooden plates – xylography, as it is called – remained the primary method of printing in China through the end of the 19th century. To this day, a printing plate or form (that is, a set of pages ready for the press) is known in Chinese as **bǎn** (板 or 版), meaning board or plank, and the most popular fonts of type for many literary purposes are still **sòngtǐ** (宋体): squarish characters based on the woodcut glyphs of the Sòng and later dynasties, rather than **kǎitǐ** (楷体), or characters based directly on the action of the Chinese brush (**Figure 1**).

If a text is carved in a slab of wood and the slab is sawn up into sections, each bearing a single character, you have what is known as movable type: individual glyphs in material form that can be endlessly rearranged into different texts. **Huóbǎn** (活板), the Chinese term for movable type, does in fact mean 'flowing plank' or 'living plank.' In all but its most cursive forms, Chinese script is admirably suited to this concept, because every character is conceived as occupying the same rectangular space. Every piece of type in a Chinese font can therefore be exactly the same size and mechanically interchangeable with every other. The difficulty is that the number of characters required to set any lengthy Chinese text is very large. Even the most rudimentary font needs 5000 to 6000 characters. More serious fonts run from 20 000 to 60 000. That hurdle notwithstanding, movable type was invented in China toward the middle of the Sòng dynasty (around the year 1040) and has never

Figure 1 The phrase *wényán*, 'literary language,' set in two different fonts of Chinese type. The **sòngtǐ** (宋体 'Sòng style') font, on the left, is based on Sòng, Míng and Qing dynasty characters carved by hand in wood. The **kǎitǐ** (楷体 'model style') font on the right is based on brushwritten characters of the Wèi and Jìn dynasties. *Sòng* fonts are in some sense comparable to Baroque fonts for the Latin alphabet (e.g., Caslon and Janson). They are considerably removed from their handwritten origins but have a long and firm association with the printed book. **Kǎi** fonts are closer in their way to Renaissance Latin fonts and their recent revivals (e.g., Centaur, Arrighi, and Fairbank), which clearly show their scribal roots.

Figure 2 A pair of English cases, racked up for hand composition. (After Chappell & Bringhurst, 1999.) There are 54 compartments in the lower case, 98 in the upper. The small compartments along the top of the upper case are differently used by different compositors, depending on their needs and the makeup of the font.

ceased to be used. Movable type was also employed in Korea by the early 13th century, when Korean was still written in Chinese script. Yet the labor of making and using it is so great that movable metal type has remained only a secondary method of printing Chinese.

The technology of papermaking traveled westward across Asia and reached Europe at the end of the 12th century. Xylography may have come soon after, but the earliest certain example found thus far is a bodhisattva-like image of St. Christopher captioned with a woodcut Latin couplet and dated 1423. The block was probably cut and printed in southern Germany.

There is no explicit evidence that examples or even rumors of Asian movable type reached 15th-century Europe, but by the 1440s several Europeans were aware of the idea and were actively at work on the implicit technical problems. The first of these to succeed was Johannes Gutenberg.

At first glance, the shift to movable type looks far less daunting in the Latin alphabet than it does with Chinese script, because the total number of characters required is so much smaller. The technical problems are magnified, however, because Latin letters vary in width. If letters are cast in metal, the mold must also be adjustable in width, and when text is corrected – an m exchanged for an n, for example – spatial adjustments must be made in the surrounding text. Even when no corrections are required, justifying paragraphs (that is, evening the margins, in keeping with the practice of the scribes) requires finicky spatial adjustments in every line.

Scribal justification was a highly developed skill in 15th-century Europe. It involved the selective use of abbreviations and ligatures, minute adjustment of the widths of individual letters, and the spacing of letters and words. To replicate this feat in metal type, Gutenberg cast, for the 42-line Bible (completed about 1455), a font of type six times the size of the alphabet itself. Gottfried Zedlar, who analyzed this font exhaustively at the beginning of the 20th century, found it to consist of 290 different characters. Twenty-four of these were basic lowercase letters; 24 were capitals; five were punctuation marks; the remaining 237 were abbreviations, ligatures, variants, and alternate castings differing slightly in width. Eighty percent of the font, in other words, consisted of accessories required only to justify the lines and give an even texture to the page.

As typecasting and printing spread through the European world and its colonies, larger fonts were cut to accommodate other languages and other scribal traditions. Most cursive Greek fonts, for instance, included far more ligatures than Latin fonts. At the same time, there was pressure to simplify justification, by relying far more on variation in the spaces between words than on variant forms and scribal abbreviations. Over time, hundreds of different cases and lays (that is, arrangements of type in the case) evolved to meet the needs of hand compositors. Some have preferred to set from paired cases, with majuscules and small caps in the upper case, minuscules in the lower case. Others have preferred single cases, which generally lack provision for small caps. The arrangements shown in Figures 2 and 3 are typical, but by no means universal, for compositors working in English.

Figure 3 Typical lay (arrangement) of a California job case, which has 89 compartments in all. In essence, this is a standard English lower case with a tray of capitals attached to the right side. ('Job' or 'jobbing', in 19th-century argot, means advertising and commercial rather than literary typesetting. Job cases were built for so-called 'jobbing faces', which routinely lacked small caps.)

In Europe toward the end of the 18th century, printing entered a period of accelerating technological change, driven by the urge to print more and print it faster. Beginning in the 1770s, wooden presses were replaced with presses partly made of iron. Presses made entirely of iron were introduced in 1800. Within the space of a few years, power-driven presses, papermaking machines, and the stereotype process were introduced. (Stereotyping is a means of casting one-piece replicas of entire pages of hand-set type and is especially useful for reprints and long runs on motorized iron presses, which quickly wear type out.)

Before the end of the 19th century, there were keyboard-operated typesetting machines, web presses (which print on a continuous roll of paper) and perfecting presses (which print both sides of a sheet or roll at once). Through the use of these devices, large parts of the world were increasingly immersed in a sea of printed language.

Writing itself was not immune to this epidemic of technological change. Several 18th-century engineers attempted to build a typewriter, though no one succeeded in bringing one to market until 1874. The first machines to be sold included a keyboard very similar to the QWERTY layout used today, but they could type in capital letters only, and the typescript could be read only after it was removed from the machine. Shift-key machines, which typed both caps and lowercase, appeared in 1878. By the mid-1880s, typists could see the text as it was typed. The familiar manual typewriter of yore was essentially complete by 1900, and it was only at this date that touch-typing became the professional norm.

Electric typewriters – first attempted in the 1870s – were widely used by the 1950s. The once-famous IBM Selectric, whose easily interchangeable fonts made it possible to type on a single machine in multiple alphabets (Latin and Hebrew, or roman and italic, for example), first appeared in 1961 and reigned supreme until displaced by the computer. (Indeed, Selectric typewriters were once employed as interface devices for some mainframe computers.)

While typewriters matured into electric and then electronic form, the printing press was radically transformed through marriage to the camera.

Lithography is a printing process based on chemical rather than physical distinctions between foreground and background, or inked and inkless areas. The printing surface is not necessarily stone (as the name implies), but it is necessarily smooth. Thus lithography, unlike letterpress, yields a perfectly two-dimensional result. The method was developed toward the end of the 18th century and proved immediately useful for printing illustrations and sheet music. In the 20th century, when printers could transfer text and images photographically onto a printing plate, high-speed lithography became the dominant means of printing anything and everything on paper. And for lithographic printing, physically movable type is unnecessary. Photographic images of letters are all that is required. So in the mid 20th century, phototype machines, whose fonts are made of film instead of metal, became the primary means of setting text.

The typesetting and printing industries had barely adjusted to this change when phototype and photolithography were also swept aside in favor of digital technology. In the world of the personal computer, printing has become, for the first time, something everyone can do. The process now involves primarily the electronic manipulation of coded information, yet the visible result remains what it has been for 1200 years: prefabricated letters rendered in ink on sheets of paper.

Priscianus Caesariensis (d. ca. 530)

M Passalacqua, Università 'La Sapienza,' Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

Priscian lived and taught in Constantinople (late 5th–early 6th centuries) as shown by his panegyric *De laude Anastasii imperatoris*. He must have been dead in 527, when his pupil Flavius Theodorus finished copying the *Institutiones grammaticae*, dedicated to *Iulianus consul ac patricius*, a philo-Anastasian epigrammatist.

The 18 books of *Institutiones grammaticae* (*Ars* in the manuscripts) established Priscian, along with Varro and Donatus, as a pillar of Latin grammar, especially for the innovations introduced by books 17 and 18, written following the Greeks Apollonius Dyscolus and Herodian, who had investigated Greek grammar from a morphosyntactic point of view. Priscian knew the western and eastern tradition of Latin grammar and tried reorganizing it with Greek in the background and a mass of examples (provided by Flavius Caper, 2nd century A.D.) that give evidence of the modifications of language. He maintained that one should follow practice on the basis of tradition.

It is possible to give a partial chronology of his works; to judge from cross-references, the *Institutio de nomine et pronomine et verbo* and the *Partitiones duodecim versuum Aeneidos principalium* were written after the *Institutiones*, whereas the *De figuris numerorum*, the *De metris Terentii,* and the *Praeexercitamina* were written together on the advice of Symmachus (consul in 485, killed in 525 A.D.), as shown by the dedicatory epistle. These last works fitted well with Symmachus's cultural program, which regarded the union of the Greek and the Latin elements as a winning team against the nationalist tendencies that perceived the united empire as something alien. The *Institutio de nomine* is the smaller sister of the *Institutiones* and – typologically speaking – is a '*regulae* type' grammar, a grammar that considers one or more parts of speech, focusing on classification and examples, but without quotations, different from the '*Schulgrammatik* type,' which explained each part of speech and its accidence and went on to illustrate the peculiarities of language with examples taken from the authors. This treatise won a wide popularity in the early Middle Ages, providing an essential morphological basis and complementing Donatus's grammar based on genders. It was ideal for people who needed to understand the Bible but no longer had Latin as their mother tongue. The *Institutiones,* on the other hand, reached their

Private Language Argument

D Byrne, University of Birmingham, Birmingham, UK

© 2006 Elsevier Ltd. All rights reserved.

The private language argument is the strand of Ludwig Wittgenstein's later work (in particular, 1953: §§ 243–315) in which he endeavored to demonstrate the impossibility of a language that only one person could understand – or, at any rate, as Wright (1986) suggested, that only one person could have *reason to believe* he or she understood. Early commentators, although divided over the argument's cogency, regarded it as perhaps the most powerfully subversive weapon in Wittgenstein's armory. Fashions have changed, however, and nowadays few philosophers seem to agree even on so much as whether the argument exists and, if it does, how it works. Critics satirize the legendary argument as a kind of perpetually elusive 'Philosopher's Stone' of woolly-minded pragmatism, and even Wittgensteinians tend nowadays to downplay the significance of any single *argument*, preferring to emphasize themes expounded by Wittgenstein in the surrounding passages (see Hacker, 1986; McDowell, 1989; McGinn, 1997).

The Argument's Target

Wittgenstein's interest is probably not linguistic *per se*: his intention is to attack a general conception of mind, usually labeled Cartesian. According to this picture, introspection affords thinking subjects an especially direct, observational access to their own mental states, whereas their access to the mental states of others is indirect and theoretical – a matter of inference from their behavior. This conception seems particularly compelling in regard to sensations and other phenomenal experiences.

Wittgenstein invites us to consider a subject – let us call him *PD* (Private Diarist) – who undertakes to name various types of sensations and record their occurrences in a diary. Cartesianism would seem to suggest that, to inaugurate names of sensation-types in this way, it would suffice for PD simply to "speak, or write the sign down, and at the same time ... concentrate ... attention on the sensation – and so, as it were, point to it inwardly" (Wittgenstein, 1953: § 258). The Cartesian conception also seems to suggest that subjects other than PD could have no reason to believe they understood these terms, so that a language containing them would be *private* to PD in the sense intended. By arguing that such a language is impossible, then, Wittgenstein attacks the Cartesian conception of mind that underpins it.

The Cartesian conception continues to dominate our intuitive, 'pretheoretical' view – at least of those mental states that enjoy a distinctive phenomenology. This alone ensures that it really matters whether there is a cogent private language argument. However, before addressing that question, it is also worth briefly considering which contemporary theories – of philosophy, psychology, linguistics, and so on – are threatened by the argument. Wittgensteinians frequently bemoan the widespread infection of mainstream theory in these disciplines by Cartesianism, but although there are reasonable general grounds for this complaint, it is actually quite difficult to find theories that are threatened by the private language argument *per se*.

The 'representational theory of mind' that underwrites much recent work in cognitive science and linguistics might seem the most obvious candidate. Indeed, Fodor (1975) has provocatively placed himself on the firing-line on its behalf. According to the representational theory, cognition involves the

highest level of diffusion during the Carolingian Renaissance, when scholars were ready for the classical grammatical model. The *Partitiones* is a didactic work in the footsteps of the Greek grammatical analysis of the sentence higher level students had to deal with. A didactic aim also produced the translation of the *Periegesis* by Dionysius (1087 hexameters).

Private Language Argument

D Byrne, University of Birmingham, Birmingham, UK

© 2006 Elsevier Ltd. All rights reserved.

The private language argument is the strand of Ludwig Wittgenstein's later work (in particular, 1953: §§ 243–315) in which he endeavored to demonstrate the impossibility of a language that only one person could understand – or, at any rate, as Wright (1986) suggested, that only one person could have *reason to believe* he or she understood. Early commentators, although divided over the argument's cogency, regarded it as perhaps the most powerfully subversive weapon in Wittgenstein's armory. Fashions have changed, however, and nowadays few philosophers seem to agree even on so much as whether the argument exists and, if it does, how it works. Critics satirize the legendary argument as a kind of perpetually elusive 'Philosopher's Stone' of woolly-minded pragmatism, and even Wittgensteinians tend nowadays to downplay the significance of any single *argument*, preferring to emphasize themes expounded by Wittgenstein in the surrounding passages (see Hacker, 1986; McDowell, 1989; McGinn, 1997).

The Argument's Target

Wittgenstein's interest is probably not linguistic *per se*: his intention is to attack a general conception of mind, usually labeled Cartesian. According to this picture, introspection affords thinking subjects an especially direct, observational access to their own mental states, whereas their access to the mental states of others is indirect and theoretical – a matter of inference from their behavior. This conception seems particularly compelling in regard to sensations and other phenomenal experiences.

Wittgenstein invites us to consider a subject – let us call him *PD* (Private Diarist) – who undertakes to name various types of sensations and record their occurrences in a diary. Cartesianism would seem to suggest that, to inaugurate names of sensation-types in this way, it would suffice for PD simply to "speak, or write the sign down, and at the same time ... concentrate ... attention on the sensation – and so, as it were, point to it inwardly" (Wittgenstein, 1953: § 258). The Cartesian conception also seems to suggest that subjects other than PD could have no reason to believe they understood these terms, so that a language containing them would be *private* to PD in the sense intended. By arguing that such a language is impossible, then, Wittgenstein attacks the Cartesian conception of mind that underpins it.

The Cartesian conception continues to dominate our intuitive, 'pretheoretical' view – at least of those mental states that enjoy a distinctive phenomenology. This alone ensures that it really matters whether there is a cogent private language argument. However, before addressing that question, it is also worth briefly considering which contemporary theories – of philosophy, psychology, linguistics, and so on – are threatened by the argument. Wittgensteinians frequently bemoan the widespread infection of mainstream theory in these disciplines by Cartesianism, but although there are reasonable general grounds for this complaint, it is actually quite difficult to find theories that are threatened by the private language argument *per se*.

The 'representational theory of mind' that underwrites much recent work in cognitive science and linguistics might seem the most obvious candidate. Indeed, Fodor (1975) has provocatively placed himself on the firing-line on its behalf. According to the representational theory, cognition involves the

manipulation of symbols that, like linguistic expressions, enjoy representational contents, yet that are private in the sense that those contents are not determined by anything like public conventions or criteria. As is discussed below, there is an interpretation of the private language argument that would place the notion of contentful symbols that are private in this sense in its sights, but it is not the most plausible interpretation. Meanwhile, we can already see that there is no *prima facie* tension between the representational theory and the argument's conclusion. For one thing, Fodor did not suppose that representations' contents are conferred by anything like acts of introspective ostension. Even more to the point, an advocate of the representational theory is entitled to insist that there could be good (empirical) reasons to suppose that two subjects enjoyed representations with the same content (and so to suppose that, in a sense, subjects 'understood' the same representations).

Much more vulnerable to challenge are the 'direct reference' theories of 'phenomenal concepts' recently defended by Loar (1997), Chalmers (2003), and others. The key idea here is that subjects enjoy concepts of the phenomenal qualities of their own conscious experiences whose contents are exhausted by their references. Some of these theorists suggest that such concepts are inaugurated through acts of introspective demonstration, and given the distinctive semantics they are proposed to enjoy, it is difficult to see how such concepts could fail to be private in something like the sense at issue here.

Supplementary Strands

Most of Wittgenstein's remarks in the passages generally considered to contain the private language argument do not directly address the issue identified above as central, but instead are concerned with the meanings of expressions used in public languages to talk about sensations and other mental states.

Wittgenstein held quite generally that understanding an expression is a matter of knowing and following rules that regulate how it is used in various language-involving activities – 'language games' – in which speakers participate. One thing Wittgenstein did in these passages is to emphasize the third-person uses of (public language) sensation terms. Understanding words like 'toothache' and 'pain' involves, *inter alia,* knowing what kinds of behavioral criteria sanction their third-person attribution. Therefore, at any rate, that understanding cannot be just a matter of demonstrative first-person acquaintance with pains, as a thoroughgoing Cartesian might assume. Of course, a Cartesian might reply by conceding the point about public language sensation terms, but insisting nonetheless on the possibility of distinct, privately inaugurated terms lacking third-person applications altogether.

Elsewhere in these passages, Wittgenstein made characteristic proposals to the effect that what seem superficially to be assertions may in fact be speech acts of other kinds: warnings, exclamations, 'performatives,' etc. One example is his suggestion that utterances involving (public language) sensation terms can be used to express sensations, rather than to describe them: "Here is one possibility: Words are connected with the primitive, the natural, expressions of the sensation and used in their place" (§1953: 244). Considering sentences that might seem to articulate the most fundamental features of sensations, such as 'Sensations are private,' Wittgenstein suggested that these are used to express the rules that govern the terms involved, rather than to make substantial assertions: 'Sensations are private' is comparable to "One plays patience by oneself"' (1953: § 248). These points are interesting and important; however, even if Wittgenstein is right that apparently indicative sentences featuring public language sensation terms can have these nonassertoric uses, this does not refute the Cartesian's basic belief in the possibility of a different language, in which he can privately make assertions about his own sensations.

Rules and Communities

Why, then, does Wittgenstein repudiate the possibility of a private language? His basic contention seems to be that a subject who undertook to inaugurate names for sensation-types he experiences by defining them through introspective demonstrations would not succeed in imbuing the names with genuine meaning – even 'for himself.' Yet, why not?

One point Wittgenstein makes is that, normally, inaugurating a new name requires a lot of background "stage-setting" (1953: § 257) of a kind unavailable here. For example, parents' ability to name their children depends on a background of conventions concerning the roles played by persons' names in the various language-games in which they feature. However, the Cartesian is likely to respond that PD might instate 'private conventions' of suitable kinds. Whether this is possible is really just the question at issue, so Wittgenstein owes more of an argument than is provided by a catalogue of differences between the private and public cases.

Just such an argument seems to be offered in this famous passage:

> I impress on myself the connexion between the sign and the sensation. – But 'I impress it on myself' can only mean: this process brings it about that I remember the connexion *right* in the future. But in the present case I have no criterion of correctness. One would like to say: whatever is going to seem right to me is right. And that only means that here we can't talk about 'right' (1953: § 258).

Suppose that PD experiences a sensation and attempts demonstratively to label the type of sensation it represents as 'S.' If 'S' is to be genuinely meaningful, there must be a difference between PD's later (1) correctly applying it to a sensation that really is of the same type as the first, and his (2) misapplying it by mistakenly applying it to a sensation that is really of a different type. Wittgenstein's contention seems to be that no such distinction can be sustained in this case, because PD has no 'criterion of correctness' to go on independent of his own inclinations. The question the Cartesian will want to press, however, is precisely why such a criterion must be in this way independent. The argument should not be based on an assumption that PD's judgments about whether a certain sensation is of the same phenomenal kind as the one he previously labeled 'S' are *unreliable* – that is on a general skepticism about PD's memory – for such an assumption would, once again, simply beg the question against the Cartesian.

As we saw above, Wittgenstein holds that linguistic understanding involves knowledge of rules regulating the use of terms. A striking feature of such knowledge seems to be its generality, because understanding a term involves the ability to use it in many different kinds of situations. He is particularly preoccupied with the question of how the contents of rules can be in this way general and, yet at the same time, apparently constitute objects of conscious awareness: things that speakers can "grasp in an flash" (1953: §138). Some commentators maintain that Wittgenstein proposes to resolve this tension by, in effect, denying that meanings really are objects of conscious awareness and by holding that a speaker's linguistic understanding is in the end simply a matter of her using terms in the same ways as other members of her linguistic community. According to this view, the patterns of use upon which members of a speech community converge engender 'criteria' of correct use that are in large measure independent of the judgments of individual members. Thus, in this picture, linguistic expressions generally are governed by criteria of correctness independent of individual speakers' impressions, and Wittgenstein's injunction that 'S' would be meaningful only if – *per impossible* – it could be so governed is just a special case of this general doctrine. Notice furthermore that if representation in general rests on this kind of communal convergence, then the private language argument threatens the representational theory of mind, as well as the Cartesian position discussed here.

The trouble with this interpretation of the private language argument is that the general 'communitarian' conception of rule following and meaning on which it rests is implausible. Moreover, commentators generally reject its attribution to Wittgenstein. (Wright (1980) explored the communitarian interpretation in detail and offered some defense. Kripke's (1982) notorious interpretation may be considered a version of the communitarian one, its distinctive spin being the meaning-skepticism that Kripke also attributed to Wittgenstein. See Baker and Hacker (1984) and McDowell (1984) for forceful arguments against both the view and its attribution to Wittgenstein.)

Radical Evidence-Independence and the 'Theory Response'

I have argued that, although the 'supplementary strands' of Wittgenstein's discussion highlight numerous important contrasts between ordinary public language sensation terms and the names that PD undertakes to introduce, these considerations do not motivate Wittgenstein's contention that PD *cannot* imbue the latter with genuine meaning. There is an influential conception of rule following and meaning that does provide such a motivation, but it is widely rejected, both as a theory of meaning and an interpretation of Wittgenstein. In this final section, I describe a different way to defend Wittgenstein's insistence that PD cannot inaugurate a meaningful term in the manner considered.

The crucial issue is that the Cartesian conception seems to imply that PD's beliefs about whether a current sensation is of the type he earlier labeled 'S' could be correct or incorrect, even if no evidence bearing on the matter were available. Commitment to this possibility implies an extremely strong form of realism or 'evidence-independence' both about the sensations at issue and also (this is often overlooked) the intention – the baptismal 'undertaking' – in terms of which PD is proposed to have inaugurated 'S'.

Advocates of the argument are often accused of resting illicitly on a verificationist and/or behaviorist assumption, and it is true that verificationism (in respect of mental states) and behaviorism are at odds with this radically realist picture. However, it is not necessary to subscribe to either of those views to feel uncomfortable about the degree of evidence-independence to which the Cartesian realist seems committed here. The Cartesian holds not only that

there may be truths about whether a sensation that PD has is of the type he earlier labeled 'S', for which there is no conclusive evidence, but also that such truths may obtain in the absence of any evidence whatsoever – even of the entirely nonbehavioral, introspective kind associated with the Cartesian notion of privileged introspective access. Wittgensteinians, such as Wright (1991), have argued forcibly that this degree of evidence-independence is more than our ordinary psychological notions – particularly those of intentions – can bear. Consider, for example, the idea that a subject *believes that goldfish are highly dangerous*, even though after careful reflection, she is convinced that she does not believe that, and even though all of her behavior – recorded over as long a temporal interval and in as much detail as you like – demonstrates no inclination whatsoever to avoid goldfish, to protect her loved ones from them, etc. If this idea seems absurd, then it looks as though we should also reject the radical evidence-independence of baptismal 'undertakings' to which the Cartesian seems committed.

Actually though, there is a way to question whether the Cartesian needs to be quite as rampantly realist as this. I have been working with the assumption that the only 'criterion of correctness' PD can apply is his own introspectively grounded impression of whether a current sensation is like the one he baptized 'S.' Yet, suppose PD has reflected on his sensations enough to formulate (in his private language) theories about them, concerning, for example, which types of sensations tend to cooccur during given temporal intervals and which not. Blackburn (1984) and others have suggested that commitment to well-confirmed theoretical hypotheses of this kind could give PD reason to disregard a phenomenal appearance at odds with it, just as a scientist might disregard the appearance of an experimental result at odds with accepted theory. If this is right, then PD might reasonably judge that an earlier application of 'S' to a sensation had been in error, even though his impression at the time had been that it was just like the one he initially associated with the term. This 'fallibilist' Cartesian can hold that there can be evidence of (sincere) misapplication (or indeed, of (sincere) correct application) of terms in a private language and so avoid commitment to the degree of evidence-independence described above.

The 'argument from radical investigation-independence' is the most formidable version of the private language argument, and the 'theory response' represents the most promising rejoinder. However, the response has not been developed in the kind of detail a conclusive adjudication would require. Wright (1986) delved deeper than most, arguing that the response depends on the assumption that PD's 'theory' satisfies various formal constraints that theories codifying patterns of cooccurrence and non-cooccurrence of sensations of given types over given temporal intervals are very unlikely to satisfy. However, the Cartesian is likely to hope that even if Wright is correct about theories of this particular, rather rarefied sort, a more general integration of private phenomenal concepts into a subject's thinking might engender a structure that does satisfy those constraints. (For some recent critical reaction to Wright (1986), see Bain (2004) and Byrne (in preparation).) As things stand then, the issues surrounding Wittgenstein's famous argument remain almost as open as they were a half-century ago.

Problem–Solution Patterns

M Hoey, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

Problem–solution patterns are recurrent combinations of clause relations (qv) that function together in such a way that they are perceived as having an existence independent of the relations out of which they are constructed. The classic problem–solution pattern has the components Situation–Problem–Response–Result–Evaluation, with the Situation being optional and the Result and Evaluation elements being available for conflation; there are, however, other variants, which are usefully discussed and illustrated in Jordan (1980) as they occur in factual reporting. The defining elements are the Problem (an aspect of the Situation requiring a Response) and the Response, which may be reported, projected, or recommended.

An instance of a Problem–Solution pattern is the following fabricated miniature narrative, used for illustrative purposes in Winter (1976):

(1)	I was on sentry duty.	(Situation)
	I saw the enemy approaching.	(Problem)
	I opened fire.	(Solution)
	I beat off the enemy attack.	(Positive Result, with implied Positive Evaluation).

Most linguists (e.g., Winter, 1976; Jordan, 1980, 1982, 1984; Crombie, 1985; Stein and Glenn, 1979) have used the term 'Solution'; Hoey (1979, 1983, 1986, 2001) used the term 'Response' rather than 'Solution' because the former term does not carry any implications of success. Stein and Glenn included an extra element, that of Plan, between Problem and Solution/Response.

Problem–solution patterns were perhaps first identified by Monroe Beardsley (1950) in the course of his work on practical logic, though they can be traced back under different terminology to Greek philosophy. The first linguists to discuss them as a text-organizing device may have been Young and Becker (1965), who saw problem–solution as a kind of paragraph structure, along with Topic–Restriction–Illustration. Unfortunately, their yoking the pattern to the paragraph inhibited their ability to develop their insight, since there is no special association of the pattern with paragraph structure or paragraph boundaries. Van Dijk (1977) referred in passing to the pattern as did Grimes (1975); Hutchins (1977) provided a fuller account in connection with the organization of scientific texts, relating the pattern to the work of semioticians such as Greimas (qv) (1966).

The structure of oral narrative developed by Labov (qv) (Labov and Waletzky, 1967; Labov, 1972) identifies in oral narratives the following stages: abstract–orientation–complication–action–evaluation–result. This structure has close parallels with the problem–solution pattern, with there being approximate matches between orientation and Situation, between complication and Problem, and between action and Response and an exact match between result and Result. (Despite the shared label, however, Labov's category of evaluation is rather different from Evaluation in the problem–solution pattern.) Another linguist interested in narrative structure, Robert Longacre, characterized narrative as having at the notional level the structure: aperture–setting–inciting moment–developing conflict–climax–denouement–final suspense–closure. His category of setting roughly approximates the Situation and developing conflict is close to that of Problem; climax and denouement, however, are much wider than Response and Result and/or Evaluation (Longacre, 1976, 1983, 1989).

Problem–Solution Patterns

M Hoey, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

Problem–solution patterns are recurrent combinations of clause relations (qv) that function together in such a way that they are perceived as having an existence independent of the relations out of which they are constructed. The classic problem–solution pattern has the components Situation–Problem–Response–Result–Evaluation, with the Situation being optional and the Result and Evaluation elements being available for conflation; there are, however, other variants, which are usefully discussed and illustrated in Jordan (1980) as they occur in factual reporting. The defining elements are the Problem (an aspect of the Situation requiring a Response) and the Response, which may be reported, projected, or recommended.

An instance of a Problem–Solution pattern is the following fabricated miniature narrative, used for illustrative purposes in Winter (1976):

(1)	I was on sentry duty.	(Situation)
	I saw the enemy approaching.	(Problem)
	I opened fire.	(Solution)
	I beat off the enemy attack.	(Positive Result, with implied Positive Evaluation).

Most linguists (e.g., Winter, 1976; Jordan, 1980, 1982, 1984; Crombie, 1985; Stein and Glenn, 1979) have used the term 'Solution'; Hoey (1979, 1983, 1986, 2001) used the term 'Response' rather than 'Solution' because the former term does not carry any implications of success. Stein and Glenn included an extra element, that of Plan, between Problem and Solution/Response.

Problem–solution patterns were perhaps first identified by Monroe Beardsley (1950) in the course of his work on practical logic, though they can be traced back under different terminology to Greek philosophy. The first linguists to discuss them as a text-organizing device may have been Young and Becker (1965), who saw problem–solution as a kind of paragraph structure, along with Topic–Restriction–Illustration. Unfortunately, their yoking the pattern to the paragraph inhibited their ability to develop their insight, since there is no special association of the pattern with paragraph structure or paragraph boundaries. Van Dijk (1977) referred in passing to the pattern as did Grimes (1975); Hutchins (1977) provided a fuller account in connection with the organization of scientific texts, relating the pattern to the work of semioticians such as Greimas (qv) (1966).

The structure of oral narrative developed by Labov (qv) (Labov and Waletzky, 1967; Labov, 1972) identifies in oral narratives the following stages: abstract–orientation–complication–action–evaluation–result. This structure has close parallels with the problem–solution pattern, with there being approximate matches between orientation and Situation, between complication and Problem, and between action and Response and an exact match between result and Result. (Despite the shared label, however, Labov's category of evaluation is rather different from Evaluation in the problem–solution pattern.) Another linguist interested in narrative structure, Robert Longacre, characterized narrative as having at the notional level the structure: aperture–setting–inciting moment–developing conflict–climax–denouement–final suspense–closure. His category of setting roughly approximates the Situation and developing conflict is close to that of Problem; climax and denouement, however, are much wider than Response and Result and/or Evaluation (Longacre, 1976, 1983, 1989).

Problem–solution patterns are instances of what have been termed 'culturally popular patterns' (Hoey, 2001), 'generalized schema' (Graustein and Thiele, 1987, Hoey, 2001), or 'larger clause relations' (Winter, 1977, 1994) and grew out of the largely unpublished work of Winter (e.g., 1976) and his associates. Although some linguists such as Bonnie Meyer (1975) and the story grammarians typically treat problem–solution as a text structure, the pattern has more often been seen as a strategy available to writers, rather than as a structural requirement. As such, it can be manipulated or left incomplete, depending on the genre and domain in which the text is being produced. One of the most important features of the pattern, described in some detail in Jordan (1984), is that its elements can be attached to participants within the text or outside it; Jordan referred to the result as 'people patterns.' Thus, in the fabricated examples above, the Problem belongs to the narrator labeling himself as 'I'. The Response is likewise attributed to the narrator and the narrator also reports and evaluates the Result. These attributions can be spread around, however, as in the following fabricated variant of the 'sentry duty' example:

(2) John and Jack were on sentry duty.
John saw the enemy approaching.
Jack opened fire.
Their prompt action successfully routed the enemy.

Here the Problem is identified by John but implicitly belongs to both men, the Solution/Response is attributed to Jack, and the Positive Result and Evaluation emanate from an anonymous narrator.

A Positive Result or Evaluation brings a Problem–Solution pattern to an end. A Negative Result or Evaluation also can do so, but only if the Negative Result is irreversible, as in the following version of John and Jack's story:

(3) John and Jack were on sentry duty.
John saw the enemy approaching.
Jack opened fire.
But the enemy shot them both dead.

When a Result or an Evaluation is negative but not irreversibly so, the pattern is felt to be incomplete (Hoey, 1983, 2001) as the following indicates:

(4) I was on sentry duty.
I saw the enemy approaching.
I opened fire.
This only made them angrier.

In such a case, the pattern can be said to recycle, and a further Solution/Response will be expected. Hoey (1983) noted that the recycling results in three types of multilayering: chained multilayering, where the negative Result of a Response leads to a new Problem; spiral multilayering, where the negative Result and/or Evaluation leads to a further attempt to solve the original Problem; and progressive multilayering, where the Result of a Response is partly positive and partly negative and the subsequent Response is an attempt to solve what remains of the Problem. This last type of pattern is particularly associated with scientific writing, whereas the previous two are associated more with fictions.

The fact that elements of the pattern may 'belong' to participants within the narrative permits more complex narratives to be constructed. Thus, the famous tale of Red Riding Hood, in one of its tellings, reports the Wolf as having the Problem of being hungry. His Response is to attempt to trap Red Riding Hood. This in turn becomes a Problem for Red Riding Hood. Her Response comes from outside in the form of a convenient woodcutter and this provides the Wolf with an irreversible Negative Result (he is killed).

Problem–Solution patterns have been defined broadly (e.g., Jordan, 1984) or narrowly (e.g., Hoey, 2001). Those who favor broad characterization of the main categories of the pattern can point to the simplicity of the system they operate. For them, a number of rather different kinds of initiating report may function as the statement of Problem. Those who favor narrow characterization of the categories point to the greater precision that arises from such characterization. For these linguists, the different kinds of initiating report warrant different labels. Thus, Hoey talks of Goal–Achievement patterns, such as:

(5)	I was on sentry duty.	(Situation)
	I wanted to capture the enemy sentry post.	(Goal)
	I opened fire when they were not looking.	(Means)
	I succeeded in capturing their post.	(Positive Result with Positive Evaluation)

of Opportunity-Taking patterns, such as:

(6)	I was on sentry duty.	(Situation)
	I saw the enemy were asleep.	(Opportunity)
	I opened fire.	(Taking)
	I captured their lines.	(Positive Result)

of Gap in Knowledge-Gap Filling patterns, such as:

(7)	I was on sentry duty.	(Situation)
	I did not know where the enemy were.	(Gap in Knowledge)
	I opened fire.	(Attempt at Filling)
	I could tell where they were from the noise that they made running for cover.	(Positive Result)

and of Desire Arousal–Desire Fulfillment patterns, such as:

(8) I was on holiday.	(Situation)
I saw a beautiful woman and fell in love with her.	(Desire Arousal)
I asked her to marry me.	(Attempt to fulfill Desire)
She accepted and we have been happily married for 60 years.	(Positive Result with. . .) (. . .Positive Evaluation).

All of these patterns permit a Situation, require a Response of some kind, and are brought to a conclusion with a Positive Result and/or Positive Evaluation (or an irreversible Negative Result and/or Evaluation), otherwise getting recycled. These shared features are an argument for treating them as variants of a single pattern.

On the other hand, each of these patterns has its own characteristic signaling system, whereby the pattern's presence is indicated by the writer to his or her readership. The signals of the Problem–Solution pattern are discussed in Hoey (1979, 1994), drawing on Winter (1977) in particular. Examples can be found in italics in the following fabricated example:

(9) I was on sentry duty *when* I suddenly saw a vast force of the *enemy* approaching. Not sure *what to do*, I *decided to* open fire, *hoping thereby* to *prevent* them coming any closer. *Happily*, this had the *requisite effect* and *disaster* was *averted*.

The signal *when* indicates a Situation; *enemy* and *disaster* indicate Problem; *what to do*, *decided to*, *thereby, prevent*, and *averted* are all signals of Solution/Response; *hoping*, *decided to* (again), and *requisite* point to a Plan (as in Stein and Glenn's 1979 version of the pattern); *effect* signals Result; and *requisite* (again) and *happily* signal that it is Positive (from the point of view of the narrator).

The signals of Goal–Achievement and the other patterns overlap but do not coincide with the signals of Problem–Solution, and those for Desire Arousal–Desire Fulfillment are significantly different, with the most important signals being those of positive evaluation and physical perception (*beautiful, sparkling eyes, strong jaw,* etc.). This might be seen as an argument for treating the patterns separately.

However we treat the patterns, we must take care not to assume that they inhere in the text; as with clause relations (qv), they are the product of the interaction between reader and text and therefore a pattern perceived by one reader may be different from that perceived by another. (Rowley-Jolivet, 2004, has indeed shown that problem–solution patterns can be found in the visual presentations of conference speakers in the hard sciences.) A key factor in the variation among the readers that can occur is the presence of evoking signals of the patterns. The signals just mentioned for the Desire Arousal–Desire Fulfillment pattern are culture specific. One reader may see *sparkling eyes* or *strong jaw* as a signal of Object of Desire, but another may see nothing in such descriptions. Likewise with regard to the problem–solution pattern, for perhaps the majority of readers the words *giant wave* will signal a major Problem, whereas for a few (surfers, for example) it might signal Opportunity. They are also, as the label insists, culturally popular, which means both that texts are not required to make use of them and that not every culture will favor the same patterns. Although work in contrastive rhetoric has touched on the ways that cultures might differ, there is still much to do to determine which patterns are favored in different cultural traditions.

Introduction

Mammals are an ancient and diverse lineage of vertebrates, and because humans are mammals, the study of mammalian vocal production provides a crucial context for understanding the evolution of human speech and singing. Conversely, from an acoustical and physiological viewpoint, the best understood mammalian vocalization is human speech, so theories and techniques from speech science have played an important role in increasing our understanding of the vocal production system (VPS) of other mammals. Despite a long tradition of believing that human vocal production is somehow highly distinctive from that of other mammals, converging data demonstrate that humans are using a relatively ordinary mammalian VPS to speak or sing. Indeed, in the context of the diversity of mammalian vocalizations that include ultrasonic sounds high above our hearing range (e.g., from bats or rodents) and infrasonic vocalizations far below it (e.g., from whales or elephants), along with a wide range of fascinating anatomical adaptations such as giant larynges or air sacs, humans appear decidedly normal. What is quite unusual is the way we use this apparatus, particularly our capacity for vocal imitation, and the motor control underlying human vocal production. However, even this skill is shared by a few other mammal groups.

This article provides an overview of mammalian vocal production, attending both to themes (aspects of vocalization shared by most mammals) and to variations (unusual adaptations appearing in isolated groups). I adopt a comparative, evolutionary viewpoint, beginning by emphasizing that mammals are an ancient lineage (Carroll, 1988). The ancestors of mammals, the synapsids or mammal-like reptiles, were a diverse and successful group before the evolution of dinosaurs. The earliest true mammals arose simultaneously with early dinosaurs in the late Triassic, approximately 210 million years (MY) ago. The best known of these early mammals is *Morganucodon*, a small shrew-like mammal (approximately 3–10 cm long), preserved in numerous fossils on several continents. With the rise of the dinosaurs, however, mammals entered a long twilight. For 150 MY, dinosaurs dominated the world, and mammals eked out a peripheral existence, small in size and few in number. Some mammal groups survived the massive extinction event ~65 MY ago, at the end of the

Introduction

Mammals are an ancient and diverse lineage of vertebrates, and because humans are mammals, the study of mammalian vocal production provides a crucial context for understanding the evolution of human speech and singing. Conversely, from an acoustical and physiological viewpoint, the best understood mammalian vocalization is human speech, so theories and techniques from speech science have played an important role in increasing our understanding of the vocal production system (VPS) of other mammals. Despite a long tradition of believing that human vocal production is somehow highly distinctive from that of other mammals, converging data demonstrate that humans are using a relatively ordinary mammalian VPS to speak or sing. Indeed, in the context of the diversity of mammalian vocalizations that include ultrasonic sounds high above our hearing range (e.g., from bats or rodents) and infrasonic vocalizations far below it (e.g., from whales or elephants), along with a wide range of fascinating anatomical adaptations such as giant larynges or air sacs, humans appear decidedly normal. What is quite unusual is the way we use this apparatus, particularly our capacity for vocal imitation, and the motor control underlying human vocal production. However, even this skill is shared by a few other mammal groups.

This article provides an overview of mammalian vocal production, attending both to themes (aspects of vocalization shared by most mammals) and to variations (unusual adaptations appearing in isolated groups). I adopt a comparative, evolutionary viewpoint, beginning by emphasizing that mammals are an ancient lineage (Carroll, 1988). The ancestors of mammals, the synapsids or mammal-like reptiles, were a diverse and successful group before the evolution of dinosaurs. The earliest true mammals arose simultaneously with early dinosaurs in the late Triassic, approximately 210 million years (MY) ago. The best known of these early mammals is *Morganucodon*, a small shrew-like mammal (approximately 3–10 cm long), preserved in numerous fossils on several continents. With the rise of the dinosaurs, however, mammals entered a long twilight. For 150 MY, dinosaurs dominated the world, and mammals eked out a peripheral existence, small in size and few in number. Some mammal groups survived the massive extinction event ~65 MY ago, at the end of the

Cretaceous, which wiped out the dinosaurs and many other groups. The surviving mammals then entered a phase of explosive adaptive radiation during the Cenozoic or 'Age of Mammals.' These early modern mammals quickly diversified into virtually all available niches, and by 55 MY ago all orders of extant mammals had evolved. Thus, despite the recency of mammalian dominance, the mammalian lineage itself is surprisingly old: more ancient than either birds or anurans (frogs and toads), the other large groups of highly vocal vertebrates. Thus, some basic traits of the mammalian vocal communication system (such as extra middle ear bones and laryngeal morphology) developed long ago, in the shadow of the dinosaurs.

Basic Themes in Mammal Vocal Production

All tetrapods (amphibians, reptiles, birds, and mammals) inherit from our common ancestor three key components: (1) a respiratory system with lungs; (2) a larynx that acts primarily as a quick-closing gate protecting the lungs, and often secondarily to produce sound; and (3) a supralaryngeal vocal tract that filters this sound before emitting it into the environment. Most mammals, amphibians, and reptiles have continued to use this system for vocalization, whereas birds and cetaceans (whales and dolphins) have developed novel vocal production mechanisms. The functioning of the basic mammalian VPS can be understood within the theoretical framework of the myoelastic-aerodynamic and source/filter theories developed by speech scientists (Titze, 1994).

The lungs and attendant respiratory musculature provide the pressure and air stream powering phonation. In primitive air-breathing vertebrates, the lungs were inflated by rhythmic compression of the oral cavity or 'buccal pumping,' a relatively inefficient system. Inspiration by active expansion of the thorax evolved later, powered originally by the intercostal muscles (in the common ancestor of reptiles, birds, and mammals). Mammals alone evolved a muscular diaphragm, which is a very efficient air-pumping system (Liem, 1985). Phonation is typically powered by passive deflation of the elastic lungs or, in some cases, by active compression of the intercostal and abdominal musculature. Phonation can also be powered by an inspiratory air stream (e.g., in donkeys or chimpanzees, and occasionally in ingressive human speech).

The trachea is protected by a larynx in all tetrapods, derived from the gill bars of our fish ancestors. Once our common tetrapod ancestor became terrestrial, gills were no longer useful, and their remains provided the 'spare parts' from which evolution built the larynx. This structure primitively includes sphincter-like musculature and a pair of bar-like cartilages that can be separated (for breathing) or pushed together (to seal the airway) (Negus, 1949). Although the larynx can support a wide variety of vocalizations, its function as a protective gateway remains primary. Expiration through the partially closed larynx creates a turbulent hiss, perhaps the most primitive vocalization, which virtually all tetrapods (and mammals) can produce. Very primitive mammals, such as the egg-laying echidna, can hiss. Phonation became possible after the innovation of elastic membranes within the larynx, termed 'vocal cords' in frogs and vocal reptiles (geckos, crocodilians) and 'vocal folds' in mammals. The mammalian vocal folds are unique in that they generally include within them a 'vocalis' or thyroarytenoid muscle, which results from the incorporation of additional gill bars (which make up the thyroid cartilage) and their attendant musculature (Schneider, 1964).

Although our knowledge of animal phonation is still limited, phonation in nonhumans seems to follow the principles of the myoelastic-aerodynamic theory of human phonation (Titze, 1994). The airflow from the lungs sets the vocal folds into vibration, and the rate of vibration is passively determined by the size and tension of these tissues. Vibration at a particular frequency does not typically require neural activity at that frequency. Thus, relatively normal phonation can be obtained by blowing moist air through an excised larynx in many species. However, cat purring relies on an active tensing of the vocal fold musculature at the 20 to 30 Hz fundamental frequency of the purr (Frazer Sissom *et al.*, 1991). During phonation, the movements of the vocal folds can be periodic and stable (leading to tonal sounds) or highly aperiodic or even chaotic (e.g., in screams); though such aperiodic vocalizations are rare in nonpathological human voices, they can be quite important in mammalian vocal repertoires (Fitch *et al.*, 2002).

Sounds created by the larynx must pass through the air contained in the pharyngeal, oral, and nasal cavities, collectively termed the supralaryngeal vocal tract or simply 'vocal tract.' Like any column of air, this air has mass and elasticity and vibrates preferentially at certain resonant frequencies. Vocal tract resonances are termed formants (from the Latin *formare* 'to shape'): they act as filters to shape the spectrum of the vocal output. Because all tetrapods have a vocal tract, all have formants. Formant frequencies are determined by the length and shape of the vocal tract, and large animals have long vocal tracts and low formants. Mammals are able to control the

configuration of the vocal tract. Raising the larynx into the nasal cavity, and sealing it with the mammalian epiglottis and velum, allows mammals to breathe through the nose while swallowing liquid through the mouth, an ability that is very useful during suckling (Crompton *et al.*, 1997). Most mammals normally breathe in this position, exclusively through the nose. However, by varying the position of the larynx during vocalization, mammals can change the configuration of their vocal tract, producing nasal sounds (through the nostrils), oral sounds (through the mouth), or a combination of the two. Because the nasal passages are convoluted and filled with spongy absorptive tissue, nasal sounds are much quieter than oral sounds. Cineradiographic data indicate that loud sounds are thus produced through the mouth in all mammals studied thus far (e.g., dog barks, goat bleats, pig squeals, or monkey chatters), but some soft sounds (e.g., dog whines or pig grunts) are produced through the nose (Fitch, 2000b). Thus, the lowering of the larynx into the oral cavity to produce loud sounds appears to be a homologous trait shared by most mammals.

Finally, the motor neurons controlling the vocal production system are located in the cranial nerve motor nuclei and appear to be quite conservative and shared among mammals (Jürgens, 1998). The larynx is supplied by the recurrent and superior laryngeal nerves, branches of the vagus nerve, and their motor neurons are located in the nucleus ambiguus in the brainstem. The muscles controlling the vocal tract are supplied mainly by the hypoglossal and facial nerves, with motor neurons in the corresponding motor nuclei. In all mammals tested, including humans, vocalization can be elicited via electrical stimulation of the periacqueductal gray region of the midbrain.

In summary, mammalian vocal production is based on a rather conservative tetrapod vocal production system composed of lungs, larynx, and vocal tract. The basic anatomy and function of this system are shared by humans, down to the details of laryngeal anatomy and innervation. Derived traits, shared by mammals but different from other tetrapods ('mammalian synapomorphies'), include a diaphragm for efficient ventilation of the lungs, complex vocal folds that include a vocalis muscle, and an ability to lock the larynx into the nasal passages with an epiglottis and velum. Most mammals lower the larynx into the oral cavity during loud vocalizations, thus assuming a vocal tract posture resembling that used during human speech. Thus, the primary traits differentiating human speech or song from vocalization in other mammals appear to be at the level of central neural control rather than peripheral anatomy.

Variations in the Mammalian Vocal Production System

Laryngeal and Source Modifications

Because the length of the vocal folds determines the lowest frequency at which the folds can vibrate (Titze, 1994), and long folds are thus able to produce lower frequencies, one might expect that a low fundamental would provide a reliable indication of large body size. This is indeed true if we look across a large range of species (August and Anderson, 1987): mice have high fundamentals relative to dogs, and elephants very much lower. However, from an anatomical viewpoint, the size of the larynx is not tightly constrained by body size. Thus, a huge larynx has independently evolved in many mammal species, probably in response to selection for low-pitched voices. For example, in howler monkeys (genus *Alouatta*), the larynx and hyoid have grown to fill the space between mandible and sternum, giving these small monkeys remarkably impressive low-pitched voices (Kelemen and Sade, 1960). The most extreme example of laryngeal hypertrophy is seen in the hammerhead bat *Hypsignathus monstrosus*, in which the larynx of males expands to fill the entire thoracic cavity, pushing the heart, lungs, and trachea down into the abdomen (Schneider *et al.*, 1967). A similar though less impressive increase in larynx dimensions is observed in human males and is responsible for their voice change at puberty (Titze, 1989). Even without greatly enlarging the larynx, a transformation of the vocal folds into massive vocal pads in large cats (Hast, 1989) and other mammals makes the production of very low-pitched roars possible in some large mammals.

Not surprisingly, the lowest pitched voices are possessed by the largest animals, which can produce infrasound (sounds with fundamental frequencies below the range of human hearing). Because low frequencies can travel further than high frequencies in some environments, infrasonic vocalizations probably represent the most widely broadcast animal signals in existence. Elephants produce and hear extremely low frequency 'rumbles' and other infrasonic vibrations (Langbauer *et al.*, 1991). In certain environments (e.g., open savannah with temperature inversions), such sounds are able to carry more than 10 km, leading to unusually large vocally mediated communication networks in African elephants. However, even these long-distance communication systems are dwarfed by those of the large baleen whales, which are the largest animals to have ever lived. Both fin whales and blue whale males (*Balaenoptera physalis* and *B. musculus*) produce low-frequency vocalizations with 20 Hz fundamental frequencies (Croll *et al.*, 2002), and under ideal conditions a

vocalization from a single animal can fill an entire ocean basin (Payne and Webb, 1971). The mechanism by which these low-frequency sounds are produced is unknown, but baleen whales possess a large larynx with a massive vocal fold and a laryngeal sac that allows air recirculation, making it possible that the aerodynamic/myoelastic theory applies even to these infrasonic vocalizations.

At the opposite end of the frequency spectrum, some rodents, primates, and bats can produce ultrasonic vocalizations with fundamental frequencies of 40 kHz and higher (Suthers and Fattu, 1973). Adaptations of the middle ear and cochlea allow most mammals to hear high frequencies (above 10 kHz) that are inaudible to birds or reptiles; the ability to produce sounds at those frequencies creates a 'private' communication channel for small mammals. This ability may have played a crucial role in the evolution of hearing and vocal production in early mammals during the Mesozoic, when birds and dinosaurs would have been the top predators. This 'private' channel is still exploited today by many rodents, particularly in courtship and mother–pup communication (Sales and Pye, 1974). Ultrasound is put to much more specialized use by echolocating bats, where the short wavelengths of ultrasonic vocalization make them ideal for picking out details from small objects (Griffin, 1958). The ultrasonic production mechanism has been best studied in bats, which have a highly specialized vocal membrane that extends upward from the vocal folds; when this membrane is cut experimentally, the bat becomes unable to produce ultrasonic calls (Novick and Griffin, 1961). Similar membranes exist in nonhuman primates, and the function of such membranes has been modeled computationally using the same principles as human speech (Mergell *et al.*, 1999).

Echolocation evolved independently in another group of mammals, the toothed whales (odontocete cetaceans, e.g., dolphins, porpoises, killer whales, and sperm whales). However, the broadband click-like echolocation signals used by these marine mammals are produced by a novel mechanism, the nasal bursae, which is unique to this group and still imperfectly understood (Cranford *et al.,* 1996). This complex organ system is present in all odontocetes studied, is housed in the nasal passages, and appears to require air movements to power vocal production, but can produce sound without emitting air so it must involve a system for air recirculation. It is unknown whether the nasal bursa system also produces the communicative whistles used by some odontocetes, e.g., bottlenosed dolphins, *Tursiops truncates*. Because whistles and clicks can be produced simultaneously, it remains possible (but unproven) that clicks are produced by the nasal complex, whereas whistles are produced at the larynx (Evans and Prescott, 1962).

Vocal Tract Modifications

Because the vocal tract in mammals rests within the confines of the head, and skull size and body size are tightly linked (Fitch, 2000c), the formant frequencies of the vocal tract provide a possible indicator of body size. Large animals generally have long vocal tracts and low formants. Together with demonstrations of formant perception by nonhuman mammals (Sommers *et al.*, 1992), this suggests that formants may have provided a cue to body size in primitive vertebrates (Fitch, 1997) and thus represent an ancient aspect of vocal communication. However, once a perceptual link between formants and body size was established, it becomes possible to break the anatomical link between vocal tract length and body size, lengthening the vocal tract and thus duplicating the formants of a larger animal. Some intriguing morphological adaptations have arisen to elongate the vocal tract (presumably resulting from selection to sound larger). Elongations of the nasal vocal tract are seen in the long nose of elephants or male proboscis monkeys. Vocal tract elongation can also be achieved by lowering the larynx; this is seen in extreme form in red deer, *Cervus elaphus*, which retract the larynx to the sternum during territorial roaring (Fitch and Reby, 2001). Similar descended larynges have evolved repeatedly in separate mammal groups, including koalas and all big cats. Again, a similar change occurs in human males at puberty: the larynx descends slightly to give men a longer vocal tract, and lower formants, than same-sized women (Fitch and Giedd, 1999). Vocal tract elongation has also evolved separately in several nonmammal groups, e.g., tracheal elongation in birds (Fitch, 1999) or the impressive nasal crests of hadrosaur dinosaurs (Weishampel, 1981). Thus, the descended larynx of humans, a perennial topic of discussion in language evolution (Lieberman, 1984; Fitch, 2000a), is just one of many convergent adaptations among disparate vertebrate taxa that elongate the vocal tract.

Another interesting set of vocal tract modifications is found in echolocating bats. Echolocating bats are divided into oral and nasal emitters, and many of the nasal emitters have evolved elaborate 'nose leafs' that function to form the echolocation signal into a focused beam of sound (Suthers and Fattu, 1973). The bat can thus point its echolocation signal at a target of interest, like the beam of a flashlight. In the paca, a large South American rodent, the zygomatic arches are hollow and ballooned outward, but the acoustic significance of this is unknown (Hershkovitz, 1955). Other interesting modifications of the nasal region

include the dulaa of male camels (*Camelus dromedarius*), which is an elastic extension of the velum that is blown out through the mouth like a large wet balloon during mating vocalizations (Arnautovic and Abdul Magid, 1974), or the similar extension of the nasal septum blown out through the nostrils during mating displays of the male hooded seal (*Cystophora cristata*) (Terhune and Ronald, 1973).

A final class of vocal tract modifications, vocal air sacs, is very widespread among mammals but still very poorly understood from an acoustic viewpoint. Air sacs appear to have evolved independently among many different taxa, in a bewildering variety of locations. For instance, many primates have air sacs attached directly to the larynx (Hewitt *et al.*, 2002); in many well-known primates (e.g., chimpanzees, baboons, macaques, howler monkeys) the laryngeal air sac fills a modified balloon-like hyoid bulla (Negus, 1949). The function(s) of these air sacs remains imperfectly understood; the only experimental study on primate air sacs documented decreased loudness of calls when they were punctured (Gautier, 1971). Primate air sacs are of particular interest with reference to the evolution of human vocalization, because all of our great ape cousins possess laryngeal air sacs, suggesting that our ancestors had air sacs and we have lost them in our recent evolution (Fitch, 2000a). Other groups that possess laryngeal air sacs include viscachas, seals, the baleen whales, in which the air sac probably serves in air recycling (Hosokawa, 1950) but perhaps also plays a role in coupling sound production to the environment, and bats, in which tracheal and nasal air sacs play a role in the production of echolocation signal (Suthers *et al.*, 1988). This great diversity of air sacs suggests multiple functions. More research will be necessary to understand the function of air sacs in those species that possess them before the significance of their loss in human evolution can be properly evaluated.

Neural Modifications

Humans share the basic innervation patterns and cranial motor nuclei described above with other mammals. However, humans are unusual among mammals, and unique among primates, in our ability to learn new vocalizations after hearing them produced (vocal imitation or vocal learning). Complex vocal learning abilities are also found in seals, cetaceans, and perhaps bats (Janik and Slater, 1997). A possibly unique characteristic of humans that may at least partially underlie this capacity is provided by the direct connections between motor cortex and vocal motor neurons, found in humans but not other primates (Jürgens, 1998). Thus, whereas vocal control in most mammals appears subcortical, humans can exert cortical control as well (for discussion see Jürgens, 1998). Unfortunately, little is currently known about the neural basis of vocal control in other mammalian vocal imitators, like dolphins, whales, and seals, to know whether similar neural specializations underlie vocal learning in these other lineages.

Another recently discovered change in neural control of vocalization in humans is more peripheral: MacLarnon and Hewitt (1999) found that modern humans have a larger thoracic vertebral canal than other primates, presumably linked to greater control over the muscles that have motor neurons in this area (intercostals and abdominals, but not the diaphragm). Because this is a characteristic that can be measured in fossils, this character provides an exciting possible cue to the timing of increased vocal control in the evolution of the human lineage. MacLarnon and Hewitt found that early *Homo erectus* (= *Homo ergaster*) had a thoracic cavity similar in size to that of chimpanzees or earlier hominids and concluded that increased breathing control involved in speech occurred no earlier than later *Homo erectus*.

However, it is important to realize that these changes are equally, if not more, relevant to singing. Sundberg (Sundberg, 1987) has convincingly argued that singing requires finer respiratory control than that necessary for speech. In normal conversational speech, the rate of airflow is approximately 0.2 L/s (0.1–0.3 L/s) and approximately 2 L tidal volume is utilized. With no involvement of the intercostals, and simple passive lung deflation, this would give 10 s of normal speech. But speakers normally breathe every 5 s. In contrast, phrases over 10 s are common in song, and singers often use nearly all of their approximately 5 L vital capacity. Furthermore, much greater subglottal pressures are generated during singing than speech (30–70 cm water relative to 6–15 cm water in normal speech). Most importantly, the finer control over amplitude and pitch required in singing leads to singers using all available muscles (including both sets of intercostals, the diaphragm, and the abdominal muscles), whereas speakers typically use only one set of intercostals for compensatory maneuvers during speech. Thus, an increase in fine respiratory control would seem to be more important in singing (where maintaining a constant subglottal pressure for consistent amplitude and pitch is a necessity) than in speech (where pitch is in any case varying continuously over a wide range).

Summary

In conclusion, mammals are an ancient lineage, and the approximately 4000 species of mammals have

developed a wide and fascinating range of vocal adaptations. Some of these, like a permanently descended larynx or the capacity for complex vocal learning, have evolved in parallel in humans and in other species. Others, like the air sacs attached to the larynx in all of the great apes, were lost in human evolution, but their significance is still poorly understood. Still others, such as ultrasonic and infrasonic vocalization, are far more extreme and indeed exceed human auditory perceptual capacities. Human adaptations for vocalization, including both speech and singing, thus take their place among a wide variety of similar vocal adaptations in mammals.

Introduction

Speakers of a language coin new words on the basis of other words or word-forming elements on a daily basis. For example, English speakers turn adjectives such as *blue* into nouns by adding the suffix *-ness*, yielding *blueness*, or form compounds by joining existing words, as in *computer screen*. Some of these words may eventually make it into the common vocabulary of the speakers, but many newly coined words are never more widely used.

Word-formation processes are to a large extent rule governed, but one observes that some of these processes (or affixes) are quite often used to coin new words, whereas others are less often used or not used at all for this purpose. For example, it seems that no new noun can be formed in Modern English with the help of the suffix *-th* (as in *depth* or *length*), whereas the nominal suffix *-ness*, which is similar in function, is found very often in new formations (cf. *eco-friendliness*, first attested in 1989, *Oxford English dictionary* (*OED*)).

In this sense, some morphological rules are called productive and other rules unproductive or less productive. Given the differences in productivity among different rules, several theoretical and empirical problems need to be addressed. First, what makes a given rule productive or unproductive? Second, how can the productivity of a given rule be measured and what mechanisms are responsible for the variability in the productivity of morphological processes? Third, should productivity be regarded as a theoretical primitive, i.e., a nonderivable property of word-formation rules, or an epiphenomenon, i.e., a property that results from other properties of the rule in question?

In the following, we first look at different definitions and measurements of productivity, then turn to the psycholinguistic mechanisms influencing the productivity of word-formation rules, and finally discuss pragmatic and structural restrictions on productivity.

Defining Productivity: Qualitative and Quantitative Approaches

One important theoretical question concerning the nature of productivity is whether productivity is a quantitative or a qualitative notion. Some scholars have argued that productivity is of a qualitative nature and that a process or an affix thus either has this property or not. Others view productivity as a gradual phenomenon, which means that morphological processes are either more or less productive than others and that completely unproductive or fully productive processes mark only the end-points of a scale.

Introduction

Speakers of a language coin new words on the basis of other words or word-forming elements on a daily basis. For example, English speakers turn adjectives such as *blue* into nouns by adding the suffix *-ness*, yielding *blueness*, or form compounds by joining existing words, as in *computer screen*. Some of these words may eventually make it into the common vocabulary of the speakers, but many newly coined words are never more widely used.

Word-formation processes are to a large extent rule governed, but one observes that some of these processes (or affixes) are quite often used to coin new words, whereas others are less often used or not used at all for this purpose. For example, it seems that no new noun can be formed in Modern English with the help of the suffix *-th* (as in *depth* or *length*), whereas the nominal suffix *-ness*, which is similar in function, is found very often in new formations (cf. *eco-friendliness*, first attested in 1989, *Oxford English dictionary* (*OED*)).

In this sense, some morphological rules are called productive and other rules unproductive or less productive. Given the differences in productivity among different rules, several theoretical and empirical problems need to be addressed. First, what makes a given rule productive or unproductive? Second, how can the productivity of a given rule be measured and what mechanisms are responsible for the variability in the productivity of morphological processes? Third, should productivity be regarded as a theoretical primitive, i.e., a nonderivable property of word-formation rules, or an epiphenomenon, i.e., a property that results from other properties of the rule in question?

In the following, we first look at different definitions and measurements of productivity, then turn to the psycholinguistic mechanisms influencing the productivity of word-formation rules, and finally discuss pragmatic and structural restrictions on productivity.

Defining Productivity: Qualitative and Quantitative Approaches

One important theoretical question concerning the nature of productivity is whether productivity is a quantitative or a qualitative notion. Some scholars have argued that productivity is of a qualitative nature and that a process or an affix thus either has this property or not. Others view productivity as a gradual phenomenon, which means that morphological processes are either more or less productive than others and that completely unproductive or fully productive processes mark only the end-points of a scale.

Productivity as a Qualitative Notion

The term 'productivity' as broadly defined in morphology textbooks refers to the property of an affix or a morphological process to give rise to new formations on a systematic basis (cf., for example, Adams, 1973: 197; Bauer, 1983: 18; Spencer, 1991: 49; Plag, 2003: 44). Such a definition may suggest that productivity is an all-or-nothing property of morphological processes. Following Corbin (1987), Bauer (2001) advocated such an approach, dividing productivity into two distinct phenomena, one of them qualitative, the other quantitative in nature: availability and profitability. A morphological process is available if it can be used to produce new words. "Availability is a yes/no question: either a process is available or it is not" (Bauer, 2001: 205). Profitability, on the other hand, is a quantitative notion and refers to the extent to which a morphological process gives rise to new pertinent formations.

The most problematic point concerning availability is the notion of 'morphological process' (or often called 'word-formation rule') itself. Given a set of apparently morphologically related words, it is not always clear whether one can in fact speak of a word-formation rule. In general, a rule is assumed if there is a sufficient number of regular form-meaning correspondences across a larger set of words. The theoretical status of such patterns is, however, controversial. Proponents of analogical models of word formation argue that traditional 'rules' or 'processes' are just a larger set of words that are related to one another by analogy (e.g., Becker, 1990, or, more recently, Skousen *et al.*, 2002). And analogy is also used to coin words on an individual, idiosyncratic basis. In a purely qualitative approach to productivity, an unproductive process could not give rise to new formations at all. However, supposedly unproductive processes sometimes do yield new formations, because speakers use existing derivatives to form new words by way of proportional analogy (cf. *greenth*). The problem with such rare coinages is where to draw the line between productive and unproductive processes. It is unclear how many such analogical formations would be needed to make a process productive (in the sense of 'available').

In view of these problems, a different line of research has abandoned the qualitative notion of productivity and has turned instead to the problem of how to determine exactly the profitability of word-formation processes. Different measures have been developed by which the productivity (here, profitability) of processes can be assessed, according to which completely unproductive and fully productive processes are conceived of as end-points on a continuum of productivity.

Productivity as a Quantitative Notion

As early as 1948, Bolinger explicitly put forward the idea that productivity is a probabilistic notion, defined as "the statistical readiness with which an element enters into new combinations" (p. 18). Since then, a number of productivity measures that try to mathematically model the notion of productivity have been proposed.

A widely used measure is the number of attested types (i.e., different words) with a given affix at a given point in time, for example, by counting the number of pertinent forms in an unabridged dictionary. This measure, however, is indicative of past rather than of present productivity. Thus, there may be many existing pertinent words, but present-day speakers may not use the process any more to coin new words. For instance, the nominalizing suffix *-ment* (*entertainment, punishment,* etc.) occurs in many established words of English, most of which entered the vocabulary between the mid-16th and the mid-19th centuries (e.g., Bauer, 2001: 181). Today, the suffix has ceased to be productive. Another case in point is the verb-forming suffix *-en* (as in *blacken, strengthen*, etc.), which is attested in numerous words, but hardly any of them were coined after 1900 (Plag, 1999: 98).

Aronoff (1976) proposed to calculate the ratio of actual to possible words as an index of productivity. The term 'actual word' designates existing established words, and 'possible word' refers to all words that – if formed – would be morphologically well formed according to the pertinent word-formation rule. The higher Aronoff's index, the higher the productivity of a given rule. A major weakness of this index is that it makes wrong predictions for extremely productive and completely unproductive processes. For example, for highly productive affixes such as *-ness*, the number of potential words is, in principle, infinite, which yields a very low productivity index. Unproductive rules such as *-th* nominalization pose the problem that the ratio of actual to possible words is very hard to calculate. If one considers all actual words with this suffix as possible words, the ratio equals 1, which, counterfactually, would indicate full productivity. Alternatively, if the number of possible words with this suffix is considered zero, the index cannot be computed at all.

A more promising way of determining the productivity of an affix is counting those derivatives that were newly coined in a given period, the so-called neologisms. By applying this measure to different periods of time, one can even show how productivity changes over time. Assessing the number of neologisms in a given period is, however, methodologically problematic since there is no established way of

keeping track of all the words appearing (and disappearing) within a given period of time. Scholars therefore usually rely on unabridged historical dictionaries such as the *OED*, which aim at giving thorough and complete information on all words of the language. For example, between 1900 and 1985, 284 new verbs with the suffix *-ize* were listed with their first attestations in the *OED* (Plag, 1999: Chap. 5), which is an indication of the productivity of this process. Unfortunately, unabridged historical dictionaries such as the *OED* are not available for the great majority of the world's languages, which seriously undermines the usefulness of this type of measure. Furthermore, the power of the dictionaries as a tool for measuring productivity should not be overestimated, because of the unavoidable lack of systematicity in the sampling procedure. For instance, the number of *-ness* neologisms listed in the *OED* for the 20th century ($N = 279$; Plag, 1999: 98) roughly equals the number of *-ize* neologisms, although *-ness* is generally considered much more productive than *-ize* (e.g., Plag *et al.*, 1999; Hay and Baayen, 2002). In view of the problems involved with dictionary-based measures (even if a superb dictionary such as the *OED* is available), Harald Baayen and his collaborators (1993, *et seq.*) have developed some corpus-based productivity measures, which all rely on the availability of very large electronic text corpora.

One corpus-based measure is the number of types (type frequency V), which differs from the first dictionary-based measure only in that it is calculated on the basis of a representative language sample.

To estimate current instead of past productivity, Baayen developed measures that rely heavily on forms that occur only once in a corpus, the so-called hapax legomena (or simply 'hapaxes'). In very large corpora, hapaxes tend to be unfamiliar words to the hearer or reader. The crucial point is that unfamiliar complex words can nevertheless be understood if there is an available word-formation rule. This rule then allows the decomposition of the newly encountered word into its constituent morphemes and the computation of the meaning of the derivative on the basis of the meaning of the constituents. Productive processes are therefore characterized by large numbers of low-frequency words and small numbers of high-frequency words. The many low-frequency words keep the rule alive, because they force speakers to segment the derivatives and thus strengthen the existence of the affix. Unproductive morphological categories will, in contrast, be characterized by a preponderance of words with rather high frequencies and by a small number of words with low frequencies.

Coming back to hapaxes, we can state that it is among the hapaxes (versus words that have a higher frequency) that we can expect the highest proportion of neologisms (Baayen and Renouf, 1996; Plag, 2003). In other words, the number of hapaxes of a given morphological category correlates with the number of neologisms in that category. Many hapaxes are indicative of many neologisms and hence of the productivity of the rule in question.

The size of the corpus is of crucial importance for this measure. If the corpus is too small, hapax legomena will tend to be well-known words of the language. With increasing corpus size, however, the proportion of neologisms among the hapax legomena increases, and it is precisely among the hapax legomena that the greatest number of neologisms appears. The number of hapaxes is therefore an important measure for estimating the productivity of a morphological process.

Based on the number of hapaxes, the probability of encountering new formations can be computed as follows. Baayen's 'productivity in the narrow sense' is calculated as the ratio of the number of hapaxes with a given affix and the number of all tokens containing that affix. This ratio represents the probability of finding a hitherto unattested word (i.e., 'new' in terms of the corpus) among all the words of that category. Equation (1) formalizes this (P is the 'productivity in the narrow sense', n_1^{aff} is the number of hapaxes with a given affix, and N^{aff} is the number of all tokens with that affix):

$$P = \frac{n_1^{\text{aff}}}{N^{\text{aff}}}. \tag{1}$$

A large number of hapaxes leads to a high value of P, indicating high productivity. Large numbers of high-frequency items lead to a high value of N^{aff} and hence to a small value of P, which indicates low productivity.

If one applies the different measures proposed above to a set of affixes, one can observe that the ranking of affixes differs according to the type of measure used. For example, the values provided in Plag *et al.* (1999) or Plag (2002) indicated that some suffixes that score comparatively high for one measure may score comparatively low for another measure.

Crucially, such apparent discrepancies are not a sign of the inadequacy or uselessness of these measures, but show that each measure highlights a special aspect of productivity. Compare, for example, the adverb-forming suffix *-wise* and the nominal suffix *-ness* (see Table 1).

-Wise has a small number of types V and a small number of hapaxes n_1, which indicates that the suffix is not used very often, neither in terms of different derivatives nor in terms of new formations.

Table 1 Productivity measures for *-wise* and *-ness*, taken from Plag *et al.* (1999)

	V	n_1^{aff}	N^{aff}	P	OED *neologisms*
-wise	183	128	2091	0.061	12
-ness	2466	943	106957	0.0088	279

Nevertheless, among all tokens with that suffix (i.e., N^{aff}), the number of hapaxes is quite high, leading to a high value of productivity in the narrow sense P. This is a sign of the suffix's potential to be easily used for the coinage of new forms, if need be.

The suffix *-ness*, on the contrary, scores very high in terms of type frequency V and also has many *OED* neologisms. Its P value is, however, significantly lower than that of *-wise*, because many *-ness* words are also quite frequently used (e.g., *happiness*), leading to a large number of tokens N^{aff} and thus an overall decrease of P.

The quantitative measures are subject to another important factor, the type of genre the data are taken from. Statements about productivity are usually not qualified with regard to this factor, although it is well known that certain affixes are more commonly found in certain types of text than in others. In a large-scale corpus-based study of the effect of written versus oral genres, Plag *et al.* (1999), for example, showed that, in general, derivational affixes are less productive in spoken than in written language. Schneider (2003) demonstrated that the productivity of diminutives varies according to kinds of speech act.

To summarize, a number of different measures have been developed to assess the productivity of word-formation rules. Each measure brings to the fore different aspects of morphological productivity and involves special methodological problems of data sampling and analysis.

Psycholinguistic Aspects: Productivity and the Mental Lexicon

Having established the productivity of a morphological process, a number of new questions arise. First, how do speakers know whether a process can be used to coin new words or not? In other words, what do productive processes have in common that unproductive processes do not have? And which properties of affixes give rise to different degrees of productivity? Answers to these questions are provided by recent psycholinguistic research into the nature of complex words. The central point of this research with regard to the nature of productivity is that the productivity of an affix is a reflection of the storage and processing of the complex words containing this affix.

Figure 1 Schematic representation of decomposition route vs. whole-word route in storage and access, with the prefixed derivative *impatient* as an example.

In current models of morphological processing, morphologically complex words can be stored and accessed in two ways: by direct access to the whole-word representation (the so-called 'whole-word route') and by access to the individual morphemes, involving the decomposition of the complex word (the so-called 'decomposition route') (see McQueen and Cutler, 1998, for an overview). According to some models, the two routes work in parallel in competition; in other models, only one route is applied at a time, depending on the kind of word. The two routes are schematically shown in Figure 1.

Whether a given word prefers one route over the other crucially depends on frequency. More specifically, the degree of decomposability of a given word depends on the relative frequency of the derived word and its base (Hay, 2001, 2003). Relative frequency is defined as the quotient of the frequency of the derived word to the frequency of its base:

$$f_{\text{relative}} = \frac{f_{\text{derivative}}}{f_{\text{base}}}. \qquad (2)$$

Usually, the base is more frequent than the derived word, so that the relative frequency is smaller than unity. For example, *detectable* has a frequency of 281 in the BNC, whereas its base, *detect*, has a frequency of 3,083, giving a relative frequency of 0.0911. Similarly, *loadable* has a frequency of 36 compared to a frequency of 5,797 for its base, *load* ($f_{\text{relative}} = 0.0062$) (values taken from Plag, 2002: 308). Only very few *-able* derivatives have a base that is more frequent than the derivative, for example, *deplorable* ($f_{\text{relative}} = 1.088$) or *comfortable* ($f_{\text{relative}} = 1.046$). Such a profile of relative frequencies is characteristic of productive morphological processes, for psycholinguistic reasons. In those cases where the base is much more frequent than the derivative, the base has a very strong representation, or high 'resting activation', in the mental lexicon, such that the representation of the base is much stronger than that of the derived word. This leads to a decomposition bias, since due to its high resting activation, the base will

be accessed each time the derivative enters the system. If, in contrast, the derived word is much more frequent than the base, there is a whole-word bias in parsing, because the resting activation of the base is lower than the resting activation of the derivative.

If in a morphological category there is a large preponderance of derivatives with a decomposition bias, the pertinent affix will have a strong representation and will therefore be readily available to the speaker to be used in new combinations. If, on the other hand, there is a large proportion of derivatives with a whole-word bias, the affix will not be readily available for the creation of new forms.

This reasoning finds support in empirical investigations by Hay and Baayen (2002, 2003). These studies showed that relative frequency patterns correlate with other properties of morphological categories: low relative frequency correlates with high productivity and high semantic and phonological transparency. As discussed above, productive morphological processes are characterized by a large number of low-frequency words (i.e., many hapaxes, if we speak in terms of corpora). Thus, productive processes have a preponderance of words with low relative frequencies, whereas less productive morphological categories are characterized by a preponderance of words with higher relative frequencies. Hay and Baayen (2002) investigated the segmentability of 80 English affixes and came to the conclusion that the more morphologically decomposable forms with a given affix are in the lexicon, the more productive that affix will be. Increased rates of parsing obviously lead to increased productivity.

A high proportion of decomposable words has another important effect: semantic and phonological transparency. The correlation between transparency and productivity has been established in many earlier publications (e.g., Aronoff and Schvanefeldt, 1978; Anshen and Aronoff, 1981; Cutler, 1981). The basic idea is that productive processes tend to have many semantically and phonologically transparent forms, i.e., forms whose semantics can be inferred on the basis of the meaning of the constituent morphemes and whose sound structure is characterized by a low degree of phonological integration of affix and stem. Productive categories are semantically transparent, because their derivatives favor the decomposed route, and decomposed storage strengthens the individual semantic representations of the constituent morphemes. This leaves little room for semantic drift and opacity, which frequently arise under whole-word access and storage. The relationship between phonological transparency and productivity is further substantiated in Hay and Baayen (2003), who investigated the phonotactics at the morpheme boundaries of the 80 affixes from their (2002) study. According to Saffran *et al.* (1996a, 1996b) or McQueen (1998), it can be assumed that speakers rely on phonotactics for the (pre-)processing of morphologically complex words and tend to posit morphological boundaries inside phoneme transitions that rarely occur inside monomorphemic words. For example, the phoneme combination /df/ (as in *dread-ful*) is extremely rare inside monomorphemic English words and its occurrence in any word will therefore strongly facilitate decomposition in speech perception. In contrast, combinations that are highly frequent inside morphemes, for example, /tɪ/ (as in *tip* or *instruct-ive*), will not facilitate decomposition. Since it can be assumed that decomposition in speech perception leads to decomposed storage, decomposed forms in the lexicon should lead to productivity. Hence, we expect there to be a relationship between the junctural phonotactics of an affix and the productivity of that affix. Those affixes that create a phoneme transition at their morpheme boundary that facilitates segmentation should be more productive. Hay and Baayen indeed found a significant correlation between the kind of junctural phonotactics of an affix and that affix's productivity. The more illegal the phonemic transitions created by an affix are, the more productive that affix tends to be. Thus, the phonological make-up of an affix (and thus the kind of juncture it creates) contributes probabilistically to the likelihood of decomposition and therefore to the degree of productivity.

In conclusion, it can be stated that the productivity of a morphological process can be explained in psycholinguistic terms as a syndrome of properties, with parsability, relative frequency, and semantic and phonological transparency as important factors. The productivity of an affix results, among other things, from quite complex processing factors, among which semantic and phonological transparency are also structurally determined. The semantic and phonological structures of affixes and their derivatives codetermine the processing and storage of these forms in the way outlined above. The significant role of structural factors in influencing – and constraining – productivity is the subject of the next section.

Productivity Restrictions

For a word to be coined, it must somehow be useful to the speaker who creates it. No matter which function a particular derivative serves in a particular situation (labeling, syntactic recategorization, or expression of an attitude; see Plag, 2003: 59–60), intended usefulness crucially constrains the formation of new complex words. However, not all potentially useful words

are actually created and used, which suggests that other restrictions must be at work as well. There is thus a distinction to be made between the general possibility of a new word to be formed and the opportunity to use the new word in actual speech. The former is constrained by structural factors, the latter by pragmatic factors.

Pragmatic Factors

The rise and fall of affixes such as *mini-* or *-nik* are prime examples of the fact that extralinguistic developments in society, often referred to as 'fashion', make certain elements desirable to use and therefore productive.

A pragmatic requirement that originates in what was called 'usefulness' above is the nameability requirement: concepts encoded by derivational categories are rather simple and general and typically may not be highly specific or complex. A classic example of such an improbable morphological category was given by Rose (1973: 516): "grasp NOUN in the left hand and shake vigorously while standing on the right foot in a 2.5 gallon galvanized pail of corn-meal-mush" is unlikely to occur in any language as the particular meaning of a denominal verbalizing affix.

Structural Factors

Structural factors influencing productivity concern the traditional levels of linguistic analysis, i.e., phonology, morphology, syntax, and semantics. The pertinent restrictions can be classified either as general principles affecting all processes or as process-specific restrictions.

Rule-specific restrictions demand the presence of certain properties in the base or in the derived word. Phonological constraints, to begin with, can make reference to segmental or prosodic structure, sometimes in rather intricate ways. For example, the verb-forming English suffix *-ify* attaches only to monosyllables, to words stressed on the last syllable, and to words stressed on the penultimate syllable and ending in /ɪ/.

An example of a morphological constraint can be seen with rival nominalizing suffixes in English. Every verb ending in the suffix *-ize* can be turned into a noun only by adding *-ation*. Other deverbal nominal suffixes, such as *-ment*, *-al*, and *-age*, are ruled out by this morphological restriction imposed on *-ize* derivatives (cf., for example, *colonization* versus **colonizement, *colonizal* or **colonizage*). This is a case of a base-driven restriction, since it is the base (the *-ize* verb) that demands a certain affix (*-ation*) be attached and rules out the attachment of other suffixes with the same function. Both base-driven and affix-driven restrictions seem to be necessary to account for the combinability of affixes and stems.

Semantic restrictions may also operate on bases and on derivatives. For example, derivatives in *-ee* (*employee*) must denote sentient entities, to the effect that *amputee* cannot refer to an amputated limb (see, for example, Barker, 1998 for detailed discussion).

One of the most commonly mentioned types of restriction is that referring to syntactic properties. The adjectival suffix *-able* normally attaches to verbs (as in *readable*), but not, for example, to adjectives. Another example is the nominal suffix *-ness*, which standardly attaches to adjectives (as in *fondness*), but not to verbs. Recently, the pervasiveness of such syntactic restrictions has been questioned, however (e.g., Plag, 2004).

Turning from rule-specific to more general restrictions, the notion of blocking features prominently (see Plag, 1999: Chap. 3 and Bauer, 2001: 126–143, for a discussion of other general restrictions that have been proposed in the literature). Token blocking refers to the impossibility of forming a potential regular form due to an already existing synonymous word. For example, **arrivement* is blocked by *arrival*, or **stealer* by *thief*. In contrast, type blocking refers to the impossibility of applying one rule if there is another pertinent rule (for example, *-ness* and *-ity* suffixation).

One important aspect of token blocking is that, contrary to earlier assumptions, not only idiosyncratic or simplex words (such as *thief*) can block productive formations (such as **stealer*), but that stored words in general can do so. In order to be able to block a synonymous formation, the blocking word must be sufficiently frequent. The higher the frequency of a given word, the more likely it is that the word will block a potential rival formation. Idiosyncratic words as well as regular complex words may block other forms if and only if the blocking word is stored.

Type blocking has been said to occur when a certain affix blocks the application of another affix (e.g., Aronoff, 1976). The crucial idea underlying the notion of type blocking is that synonymous rival affixes (such as *-ness, -ity,* and *-cy*) apply in a more or less restricted domain. The most unrestricted affix is the so-called general case (in our example *-ness*), whereas affixes with a more restricted domain are the so-called special cases (*-ity* or *-cy*). Type blocking would occur when the more special affix precludes the application of the more general affix, which is thus an instance of Panini's law or the elsewhere principle. However, type blocking cannot accurately account for the patterning of the data. For example, Aronoff (1976: 53) claimed that derivatives with nominal

-ness are ill formed in all those cases where the base adjective ends in *-ate, -ent*, or *-ant*, hence, the contrast between supposedly well-formed *decency* and supposedly ill-formed **decentness*. This account is, however, problematic. Riddle (1985) has shown that *-ness* and its putative rivals *-ity* or *-cy* are not really synonymous, so that blocking could – if at all – occur only in those cases where the meaning differences would be neutralized. In general, *-ness* formations tend to denote an embodied attribute, property, or trait, whereas *-ity* formations refer to an abstract or concrete entity. Hence, *-ity* and *-ness* lack the prerequisite for type blocking, synonymy. Another problem is the status of forms such as *decentness*. This form is listed, for example, in *Webster's third new international dictionary of the English language* and *Roget's II: The new thesaurus*, and an Internet search provided 322 occurrences, which indicates that *decentness* is not at all ill formed. Furthermore, the general case *-ness* is not systematically curtailed by *-ity* or *-cy*, as shown by the many attested doublets (e.g., *destructiveness–destructivity, discoursiveness–discoursivity, exclusiveness–exclusivity,* all from the *OED*). The final problem with putative cases of type blocking is that it is often impossible to distinguish them from token blocking. Thus, putative avoidance of *decentness* could be a case of token blocking, since the word *decency* is part of the lexicon of many speakers, and hence capable of token blocking.

In summary, type blocking as a general factor constraining productivity is to be rejected. Token blocking, however, is a relevant principled mechanism that restricts the productivity of affixes by preventing the formation of complex rival synonymous forms.

Conclusion

The productivity of a word-formation process can be defined as its general potential to be used to create new words and as the degree to which this potential is exploited by the speakers. Productivity can be assessed by various measures, both corpus-based and dictionary-based. Productivity emerges from the mental lexicon as the result of parsability, relative frequency, and semantic and phonological transparency. Apart from constraints on processing and usage, structural constraints also play an important role in restricting productivity. Possible words of a given morphological category must conform to very specific phonological, morphological, semantic, and syntactic requirements, which impose limits on productivity. Finally, in addition to rule-specific restrictions, the general mechanism of token blocking prevents complex words from being formed if a synonymous word is already available in the speaker's mental lexicon.

Projection Problem

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The projection problem was considered the central problem in presupposition theory during the early 1970s. After that, it was realized that it is automatically accounted for in terms of a wider theory of presupposition and discourse semantics.

The projection problem is posed by the behavior of presuppositions of embedded clauses. The property of presuppositions to be sometimes preserved through embeddings, albeit often in a weakened form, is called *projection*. The projection problem consists of formulating the conditions under which the presuppositions of an embedded clause (a) are kept as presuppositions of the superordinate structure, or (b) remain as an invited inference that can be overruled by context, or (c) are canceled.

Let sentence *B* presuppose sentence *A* ($B \gg A$); then *B* also semantically entails *A* ($B \models A$). Now, when B_A (*B* presupposing *A*) is embedded in a larger sentence *C*, then either $C \models B_A$ or $C \not\models B_A$. When $C \models B_A$, then $C \gg A$. That is, when B_A is entailed (or presupposed) by its embedding clause *C*, then *C* inherits the presuppositions of B_A. For example, (1a) $\gg$ (1b) and (1c) $\models$ (1a). Therefore, (1c) $\gg$ (1b):

(1a) Susan got her money back.
(1b) Susan had lost her money.
(1c) Susan managed to get her money back.

The operator *and* is the only exception. When a conjunction is of the form 'A and B_A' (the first conjunct expresses the presupposition of the second), B_A is entailed, yet *A* is not presupposed. Thus, although (1a) $\gg$ (1b) and (2) $\models$ (1a), (2) $\not\gg$ (1b), but it is still so that (2) $\models$ (1b):

(2) Susan had lost her money and she got it back.

Entailment is thus 'stronger' than presupposition in the sense that entailments are properties of sets or series of sentences, whereas presuppositions are properties of single sentences.

When $C \not\models B_A$ (and hence $C \not\gg B_A$), then, in all cases but one, $C \not\models A$ (and hence $C \not\gg A$). The one exception is negation: (3a) $\gg$ (3b) and (3c) $\gg$ (3b), even though, obviously, (3c) $\not\models$ (3a):

(3a) Only Jim laughed.
(3b) Jim laughed.
(3c) Not only Jim laughed.

This answers question (a), except for the behavior of *and* and *not*.

When entailment is lost *A* often remains an *invited inference* of *C* ($C > A$). When $C > A$, the suggestion is that *A* is true if *C* is true, but the inference can be overruled by contextual factors. Moreover, when $C > A$, *A* followed by *C* makes for an orderly bit of discourse, just as when $C \gg A$. Presuppositions thus differ from other entailments, which are never kept as invited inferences across nonentailing embeddings. Thus, (4a) $\gg$ (4b) and (4c) $\not\models$ (4a), but (4c) $>$ (4b).

Projection Problem

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The projection problem was considered the central problem in presupposition theory during the early 1970s. After that, it was realized that it is automatically accounted for in terms of a wider theory of presupposition and discourse semantics.

The projection problem is posed by the behavior of presuppositions of embedded clauses. The property of presuppositions to be sometimes preserved through embeddings, albeit often in a weakened form, is called *projection*. The projection problem consists of formulating the conditions under which the presuppositions of an embedded clause (a) are kept as presuppositions of the superordinate structure, or (b) remain as an invited inference that can be overruled by context, or (c) are canceled.

Let sentence *B* presuppose sentence *A* ($B \gg A$); then *B* also semantically entails *A* ($B \models A$). Now, when B_A (*B* presupposing *A*) is embedded in a larger sentence *C*, then either $C \models B_A$ or $C \not\models B_A$. When $C \models B_A$, then $C \gg A$. That is, when B_A is entailed (or presupposed) by its embedding clause *C*, then *C* inherits the presuppositions of B_A. For example, (1a) $\gg$ (1b) and (1c) $\models$ (1a). Therefore, (1c) $\gg$ (1b):

(1a) Susan got her money back.
(1b) Susan had lost her money.
(1c) Susan managed to get her money back.

The operator *and* is the only exception. When a conjunction is of the form 'A and B_A' (the first conjunct expresses the presupposition of the second), B_A is entailed, yet *A* is not presupposed. Thus, although (1a) $\gg$ (1b) and (2) $\models$ (1a), (2) $\not\gg$ (1b), but it is still so that (2) $\models$ (1b):

(2) Susan had lost her money and she got it back.

Entailment is thus 'stronger' than presupposition in the sense that entailments are properties of sets or series of sentences, whereas presuppositions are properties of single sentences.

When $C \not\models B_A$ (and hence $C \not\gg B_A$), then, in all cases but one, $C \not\models A$ (and hence $C \not\gg A$). The one exception is negation: (3a) $\gg$ (3b) and (3c) $\gg$ (3b), even though, obviously, (3c) $\not\models$ (3a):

(3a) Only Jim laughed.
(3b) Jim laughed.
(3c) Not only Jim laughed.

This answers question (a), except for the behavior of *and* and *not*.

When entailment is lost *A* often remains an *invited inference* of *C* ($C > A$). When $C > A$, the suggestion is that *A* is true if *C* is true, but the inference can be overruled by contextual factors. Moreover, when $C > A$, *A* followed by *C* makes for an orderly bit of discourse, just as when $C \gg A$. Presuppositions thus differ from other entailments, which are never kept as invited inferences across nonentailing embeddings. Thus, (4a) $\gg$ (4b) and (4c) $\not\models$ (4a), but (4c) $>$ (4b).

This inference is overruled in (4d), which says that Harry wrongly believes that he has a son, and that this (nonexistent) son lives in Kentucky:

(4a) Harry's son lives in Kentucky.
(4b) Harry has a son.
(4c) Harry believes that his son lives in Kentucky.
(4d) Harry has no son, but he believes that he has one and that this son lives in Kentucky.

In the case of *if* the antecedent clause may express the presupposition of the consequent clause. In such cases, the presupposition is canceled, as in (5a). Similarly for *or*: one disjunct may cancel the presupposition of the other, as in (5b):

(5a) If Harry has a son, his son lives in Kentucky.
(5b) Either Harry has no son, or his son lives in Kentucky.

Not is again problematic in that it normally lets presuppositions project as invited inferences, but occasionally as full presuppositions, as in (3c), and occasionally also cancels them altogether, as in (6), which contains the positive polarity item *hardly* (positive polarity items only allow for a higher *not* if some presupposition is canceled):

(6) Bob does NOT hardly feed his dog: he doesn't even have one.

This gives an idea of what is involved in the questions (b) and (c). None of the proposals made in the literature has been able to offer a principled account of the projection properties of presupposition.

The first proposal was made by Langendoen and Savin (1971), who proposed that presuppositions are always maintained as such through embeddings, which is observationally inadequate. A more sophisticated theory was proposed by Karttunen in various publications. Observing that projection properties depend on the embedding operator, he distinguished between *plugs*, *holes,* and *filters*. Plugs are operators that always cancel presuppositions and invited inferences. Holes are operators that always let them through, either as presuppositions or as inferences (e.g., *believe*). Filters sometimes let them through and sometimes do not (e.g., *not*, *if*, *or*). He did not succeed, however, in formulating adequate conditions for the three classes, in particular the filters. It is now generally agreed that though Karttunen's work focused attention on these phenomena, it was too taxonomic and failed to provide a satisfactory solution.

The second main approach is Gazdar (1979). Here, presuppositions are brought together with entailments and implicatures into one system of hierarchically ordered cancellation conditions. The notion of entailment is classical, and so is the logic administering it. In principle, all implicatures and presuppositions are deemed to 'survive' through embeddings, unless there is a conflict, in which case selective canceling ('filtering') takes place. Implicatures and presuppositions of the smallest possible sentential structures are spelled, respectively, 'im-plicatures' and 'pre-suppositions.' Only when they have made it to the surface, through all embeddings, is the spelling 'implicature' and 'presupposition' (without hyphen) used.

Im-plicatures are scalar or clausal. Scalar im-plicatures are of the kind familiar in pragmatics: an expression *e* occupying a position on a semantic scale *s* generates the scalar im-plicature 'not stronger than *e*'. Thus, *Some men died* has the scalar im-plicature K(not all men died) – read as 'for all the speaker knows, not all men died.' Clausal im-plicatures are generated by sentences *A* containing as a subpart some clause *B* such that *A* entails neither *B* nor $\neg B$. The im-plicature is then of the form $P(B) \wedge P(\neg B$, 'P' standing for the epistemic possibility operator (Gazdar, 1979: 58–59). Thus, *Nob thinks that Bob is brave* clausally im-plicates P(Bob is brave) $\wedge$ P(Bob is not brave). A pre-supposition is an implicature that is also semantically entailed. A presupposition, as a property of a possibly complex sentence, may or may not be entailed.

The filtering mechanism works as follows. Given a sentence *A* an inventory is made of its eventual entailments (**E**), of its accumulated im-plicatures (**I**), and of its accumulated pre-suppositions (**P**). If **E** contains contrary entailments, *A* is uninterpretable. If some $\mathbf{e} \in \mathbf{E}$ is incompatible with any $\mathbf{i} \in \mathbf{I}$ or $\mathbf{p} \in \mathbf{P}$, **i** or **p** is canceled and *A* remains interpretable in all contexts compatible with **E**. If some $\mathbf{i} \in \mathbf{I}$ is incompatible with some $\mathbf{p} \in \mathbf{P}$, **p** is canceled and **i** remains. Mutually incompatible im-plicatures or pre-suppositions cancel each other. Entailments thus take precedence over im-plicatures and im-plicatures over pre-suppositions. For example, 'if A then B' generates the im-plicature $P(A) \wedge (P(\text{not-}A) \wedge P(B) \wedge P(\text{not-}B)$, all four being admissible knowledge states. If *B* presupposes *A*, the pre-supposition K(A) is canceled by the incompatible im-plicature P(not-A).

Gazdar was among the first to stress the relevance of presupposition for an incremental theory of discourse semantics. Given a context (i.e., a set of propositions) **C**, a newly presented sentence *A* is incremented to **C**, thus creating a new context **C′** for a following sentence. Eventual presuppositions (including invited inferences) are incremented to **C** prior to their carrier sentences (Gazdar, 1979: 132). Incremented propositions are considered linked by *and*. When $\mathbf{C} \wedge A$ is inconsistent, *A* is uninterpretable

in **C**. When **C** is incompatible with some $\mathbf{i} \in \mathbf{I}$ or $\mathbf{p} \in \mathbf{P}$ ($A \not\models p$), then **i** or **p** is filtered out and *A* loses that implicature or pre-supposition in **C**. This incremental aspect of Gazdar's theory is an extension of the filtering mechanism to any context **C**, as the same results are obtained by conjoining *A* with (the sentences expressing) the propositions in **C**.

A more unifying view is obtained when the principles of Maximal Unity (MaU) and Minimal Size (MiS) are assumed for **D**s. MaU entails a maximal leveling of information through the subdomains of a discourse domain **D**. MiS entails that what has been incremented must not be doubted again. MaU ensures that besides what is explicitly incremented in a subdomain $\mathbf{D_n}$, $\mathbf{D_n}$ also contains all information previously stored in higher domains, including the commitment domain $\mathbf{D_o}$, provided $\mathbf{D_n}$ remains consistent. This *downward percolation* allows the use of discourse addresses and increments from higher domains in lower domains. The counterpart of downward percolation is the *upward percolation* of presuppositions from lower to higher domains unless stopped by inconsistency with either explicitly stored information or available background (scenario) knowledge. Thus, in (4c) MaU generates the invited inferences that Harry has a son and that there is a place called 'Kentucky.' The invited inference that Harry has a son is blocked in (4d) because the higher domain says that he has no son.

Some subdomains are subject to the requirement that they be themselves incrementable to their superordinate domain. The subdomain created by epistemic *may*, for example, require that what is said to be possible is a proper potential increment to $\mathbf{D_o}$, and must thus be consistent with $\mathbf{D_o}$, but not already contained in it. Likewise for the discourse-splitter *or* and the hedger *if*. 'A or B' is incremented as two alternative subdomains 'A' and 'not-A and B.' Both alternatives must be incrementable to $\mathbf{D_o}$. This condition automatically blocks the projection of (4b), 'Harry has a son,' from the disjunction (5b): if (4b) were added to $\mathbf{D_o}$ the first alternative would not be incrementable. Analogously for conditionals, as in (5a): there is no invited inference that Harry has a son because if there were, it could not be doubted again by *if* in virtue of MiS.

And is primarily a discourse-incrementer; its being a truth function is derived from that (which explains why *and* does not like to stand under negation). $A \wedge BA$ does not presuppose (or invite the inference) A because if it did, *A* would have to be incremented twice, which would violate MiS.

Not(BA) normally preserves the presupposition *A* as an invited inference, because *BA* under *not* must have the right papers for the current **D**. Yet *not* is special. First, it is not allowed over positive polarity items and is required by negative polarity items. Then, it preserves the full entailing presupposition in all cases where it occurs in 'noncanonical' position (for English, not in construction with the finite verb, as in (3c) above) and also when it stands over clefts or pseudoclefts, and when a factive *that*-clause stands in front position as in (7), which fully presupposes that Janet's brother was arrested:

(7) That her brother was arrested did not surprise Janet.

There also is a presupposition-canceling metalinguistic NOT, which says of its argument sentence *BA* that it does not fit into **D** because *A* clashes with **D**, as in (6). This NOT requires heavy accent, must stand in canonical position, and allows for positive polarity items, like *hardly*. How *not* and NOT relate to each other is still a matter of debate.

Gazdar's analysis can thus be perfected and be seen to follow from a postulated mechanism of discourse incrementation.

Pronouns

A Saxena, Uppsala University, Uppsala, Sweden

© 2006 Elsevier Ltd. All rights reserved.

According to the traditional definition (from the Web version of Webster's 1913 dictionary), a pronoun is "[a] word used instead of a noun or name, to avoid the repetition of it. The personal pronouns in English are I, thou or you, he, she, it, we, ye, and they."

Pronouns are a special case of the more general linguistic category 'proforms,' i.e., (semantically empty or nearly so) function words that replace (lexical content-bearing) syntactic units of a particular category. In the case of pronouns, the units in question are NPs or modifiers of the head noun in an NP, i.e., adjective phrases, quantifiers, or determiners. Even the most prototypical personal pronouns can be said to fit this definition if we say that the replaced NPs are the names of the speaker(s) or addressee(s), etc., (as implied in the Webster definition), or possibly expressions like 'the speaker(s),' etc.

Since Latin grammar – whence the term 'pronoun' (*pronomen*) originates – categorizes nouns and adjectives as special cases of 'names' (*nomina*), it is not surprising that 'pronouns' and 'promodifiers,' too, are considered to form one part of speech.

Hence, pronouns form a quite heterogeneous class of words. The most prototypical members of this class are the personal pronouns, among which are normally counted also possessive (corresponding to English *my* ~ *mine*, *her* ~ *hers*, etc.), reflexive (e.g., *themselves*), and reciprocal (e.g., *each other*) pronouns. Depending on the language and grammatical tradition, at least the following other kinds of pronouns are also commonly recognized:

- demonstrative pronouns, which identify or specify a noun. The number of spatial distinctions made varies among languages, but at least 'here' (near speaker) and 'there' (away from speaker) is commonly found, yielding the English opposition *this* ~ *that* (*see* **Demonstratives**).
- relative pronouns, which form relative clauses, i.e., clauses serving as modifiers in the NP.
- interrogative pronouns; '*wh*-items'; used to ask questions (*see* **Semantics of Interrogatives**).
- indefinite pronouns, which form a very heterogeneous group, prototypically encompassing items expressing indefinite reference (such as English *something*, *anything*, *nothing*), but commonly also taken to include quantifiers such as *many*, *every*, generic pronouns such as German *man* 'one, you (impersonal),' and relational expressions such as *other*, *same* (*see* **Indefinite Pronouns**).

Sometimes the corresponding proadverbs (or 'pronominal adverbs') are grouped together with pronouns in grammars, i.e., interrogative pronouns such as English *who* and *what*, are considered as being of a kind with interrogative adverbs like *where*, *when*, and *how*.

Pronouns are function words, which means that they constitute a closed word class, with a small set of members. In many languages, the text frequency of pronouns is high, and consistent with this frequency, pronouns tend to have a fairly simple phonological structure, normally one or two syllables with simple consonants or consonant clusters, although longer and more complicated pronouns do exist, as do word-formation patterns restricted to pronouns (and pronominal adverbs), such as Swedish/English *någonting/something* ~ *anything* ~ *ingenting/nothing*, or multi-word pronouns, like Swedish *den här* 'this' ~ *den där* 'that'; Swedish/Polish *vad som helst/byle co* 'anything (whatsoever)' ~ *vem som helst/byle kto* 'anybody (whosoever).'

The prototypical function of pronouns is a 'signpost-like' one: A pronoun serves to identify referents, not by describing or naming them, but by 'pointing them out,' as it were. There are two kinds of identification often distinguished in the literature, 'deictic' and 'phoric.' A deictic pronoun (or a deictic usage of a pronoun) refers directly to something in the world: If I say *He did it!* pointing at a man standing next to me, I am using the personal pronoun *he* deictically. A phoric (usage of a) pronoun, on the other hand, provides an index to some part of the discourse in which it occurs; it 'corefers' rather than refers (hence this indexing mechanism is often called 'coreference' in the literature). The phoric uses of pronouns are demonstrative and personal pronouns used to refer to complete predications (as in *He admitted that he did it. **This** means that I am innocent.*), and reference to lexical NPs elsewhere in the discourse: reflexive and reciprocal pronouns used intrasententially, and, most prototypically, 'anaphoric' (the pronoun comes after the lexical NP, called the *antecedent*) and 'cataphoric' (the pronoun anticipates the lexical NP) reference. Whereas a full NP will pick out its referent by describing it lexically (e.g., *the house on the hill*), a phoric pronoun will provide as much structural information as is needed and allowed by the grammar of the language, so that the listener can pick out the intended NP in the discourse. As a consequence, phoric pronouns will often be capable of richer inflectional expression than nouns. That this capability should be so seems quite natural in the case of agreement features, such as gender/noun class, number, and occasionally posture and spatial position and

movement. Thus, in the Swedish sentence *Tallriken föll i golvet och* ***den*** *gick sönder* 'The plate fell to the floor and **it** broke,' the phoric pronoun *den* 'it' is nonneuter singular, and given only this sentence as context, it can only refer to the likewise nonneuter singular NP *tallriken* 'the plate,' but not to the neuter singular NP *golvet* 'the floor,' which would have required the use of the phoric pronoun *det* 'it (neuter sg)' instead. We should note at this point, that lexical NPs, too, are often used anaphorically; especially common is the anaphoric use of a hyperonym (more general term) of the antecedent NP, a mechanism that provides a natural starting point for the grammaticalization of general nouns into pronouns (see below) (*see* **Anaphora, Cataphora, Exophora, Logophoricity**).

However, pronouns tend to express other grammatical features as well as express them to a higher degree than nouns. Thus, in the continental Scandinavian languages Danish, Norwegian-Bokmål (Norwegian, Bokmål), Norwegian-Nynorsk (Norwegian, Nynorsk), and Swedish, in English, in French, and in Macedonian, and many other languages, personal pronouns are inflected for case (subject, direct object, dative), a category completely lacking in nouns in those languages. This tendency is less easily explained by the need for discourse-internal reference, but may be a natural stage on the way toward the grammaticalization of phoric pronouns as agreement affixes on verbs. It has been noted, for example, that in some languages, such as Tuscarora (an Iroquoian language spoken in North America), sometimes called pronominal argument languages, lexical NPs – neither expressing case nor showing syntactic function by word order – behave like loose adjuncts to clauses, rather than full syntactic arguments of the verb, a role usurped, as it were, by agreement morphemes (prefixes in Tuscarora), which express case and coindex any lexical NPs by agreement features.

In some languages, subject pronouns express the category of 'switch reference,' where the form of the subject pronoun shows if the subject of the current (dependent) clause is the same as in the preceding (main) clause (SS), or a different one (DS), as in the following two examples from Diyari (Dieri) (Australia):

(1) nhulu nganthi pardaka-rna warrayi,
he-ERG meat-ABS bring-PART AUX
thanali thayi-lha
they-ERG eat-SS
'He brought the meat for them (him and others) to eat'

(2) nhulu nganthi pardaka-rna warrayi,
thanali thayi-rnanthu
eat-DS
'He brought the meat for them (others) to eat'
(From Wiesemann, 1986: 458)

Further, pronouns – both deictic and phoric – often express such features as distance (from speaker and/or addressee), visibility, and politeness/social distance (between speaker and addressee, and between speaker and persons mentioned).

Compared to nouns and adjectives, pronouns tend to have more irregular and often highly characteristic inflectional patterns.

How many persons personal pronoun systems express varies between languages. A very common system has three persons (first, second, third) in two numbers (singular and plural), for a total of six person/number slots in the paradigm. Often, a dual number is found in addition to singular and plural, increasing the number of person/number combinations to nine. Some personal pronoun systems have trial number, and a quadral number exists at least in Sursurunga, an Austronesian language spoken in Papua New Guinea. In nonsingular nonthird-person forms, the distinction between inclusive and exclusive forms is often encountered, as in Huallaga Quechua (Quechua, Huánuco, Huallaga) *noqakuna* 'we, excluding you, the addressee(s)' ~ *noqanchi:* 'we, including you, the addressee(s).'

One of the more elaborate person systems described is that of Ghomala' (Ghomálá'), a Bantu language spoken in Cameroon, evidencing free subject forms of personal pronouns encoding the following persons and combinations of persons:

1sg, 1sg + 2sg, 1sg + 3sg, 1pl + 2sg, 1pl + 2pl, 1pl + 3sg, 1pl + 3pl, 1pl
2sg, 2sg + 3sg, 2pl + 3sg, 2pl + 3pl, 2pl
3sg, 3sg + 3sg, 3pl
1sg + 2sg + 3sg, 1pl + 2sg + 3sg, 1pl + 2pl + 3sg, 1pl + 2pl + 3pl

It is not always easy to formulate necessary and sufficient criteria for distinguishing pronouns from other linguistic categories. Pronouns share many characteristics both with nouns and with agreement clitics and affixes. This feature becomes especially clear in cross-linguistic and typological studies, where the same function that is accomplished with pronouns in one language utilizes some other mechanism in another language. If verbs in some language show rich agreement morphology (encompassing one or more core arguments of the verb), pronouns may be used mostly for emphasis. Where agreement morphology is missing, as in Swedish, pronouns may be required even with argumentless verbs (analogous to expletive *it* in English): ***Det*** *blåser* '**It** blows (= there is a wind/the wind is blowing),' cf. the Finnish version of the same utterance: *Tuulee* 'Blows,' with no pronoun at all, only third-person singular agreement morphology on the verb. Similarly, a prepositional phrase containing a pronoun NP in English may instead be

expressed with an adposition–possessive affix combination in some other language, e.g., Hungarian *neked* (*nek-ed* 'DATIVE–2SG') 'to you,' cf. *[az] embernek* (*ember-nek* 'man-DATIVE') 'to [the] man' and embered (*ember-ed* 'man–2SG') 'your man.' This difference means that the text frequency of pronouns (at least phoric pronouns) will vary widely among languages, depending on structural factors such as the ones just cited.

Further, linguists have noted that core argument pronouns seem to appear with different frequencies, depending on their grammatical function. One proposed generalization concerns the form of core argument NPs in languages, stating that lexical A(gents) – i.e., typically subjects in transitive clauses – will tend to be avoided, i.e., A will tend to be expressed by a pronoun or nothing (zero anaphora). This generalization means that there should be a tendency for overuse of pronouns (or only agreement morphology) in the A role across languages. For example, examining a traditional narrative in Kinnauri (a Tibeto-Burman language spoken in northern India), comprising a total of 420 clauses containing altogether 293 A arguments, we find that only about one-fifth, or 19% of the A arguments are in the form of lexical NPs, and the remainder are expressed by zero anaphora (73%) or pronouns (8%).

Students of grammaticalization have noted a frequently occuring grammaticalization pathway from nouns over pronouns and clitics to agreement morphology, as well as a partial pathway from demonstrative pronoun over third-person independent pronoun, clitic pronoun, and finally agreement suffix. However, it should be mentioned here that there are other sources for agreement morphology as well, and not only pronouns.

The noun component of indefinite or polite/honorific personal pronouns is often still discernible, e.g., *-thing*, *-body* in English indefinite pronouns, Swedish/German generic *man* (<*man/Mann* 'man'), Polish (nominative forms) *pan* (masc.sg.) ~*pani* (fem.sg.) ~*panowie* (masc.pl.) ~*panie* (fem.pl.) ~*państwo* (mixed gender pl.) 'you (polite)' (<'lord(s) ~lady(/ies) ~lordship'). Even though nominally a closed functional category, pronouns are subject to rather quick diachronic change, compared to other functional categories, resulting in even fairly closely related languages showing considerable differences in their pronoun inventories. Here, the first- and second-person personal pronouns are least susceptible to change, whereas third-person personal pronouns are renewed a bit more often (cf. English *he* ~ *she* with *er* ~ *sie* in closely related German; cf. also English *they,* which is a recent loan from Scandinavian), and the indefinite pronouns, finally, seem to show the most rapid turnover over time.

Proper Names: Linguistic Status

P Hanks, Berlin-Brandenburg Academy of Sciences, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Texts are full of names, yet comparatively little attention has been devoted by linguists to their study as linguistic items. Names, especially place names and personal names, are studied more often as historical items, in which linguistic scholarship plays an ancillary role. This may be because it is assumed that there is little to say about the role of names in the system and structure of a language. However that may be, there is much to be said about sociolinguistic and pragmatic aspects (see, e.g., Allerton, 1987; Alford, 1988), while the morphological history of names can shed light – or at least sidelights – on the development of a language, its dialects, and its language contacts (*see* **Personal Names** and **Place Names**).

Words and Names

How are names different from words? Words typically pick out objects and events in the world by virtue of particular attributes, according to which they are assigned to the category designated by the word. If some animate entity is referred to as a *dog*, it may be assumed to have doglike properties; e.g., it will be a domestic animal that has a tail and barks. This is because the word *dog* is semantically content-full. Names, on the other hand, are semantically empty. They identify individuals directly. They function as interface points between language as system and particular individuals in the world. There is nothing semantic about the name *Scruff* or *Rover* that would justify any assumption about whether the bearer is a dog, a cat, a human, or a city (all of which may be named entities). It is not the case that a name given to a dog necessary implies that the bearer has doglike properties. Names are conventional identifiers; their bestowal on individuals is an arbitrary linguistic act.

Nevertheless, probabilistic inferences are regularly and often correctly drawn on the grounds of morphology, syntagmatic context, and onomastic convention. A linguistic item that ends in *-ton*, used in an English context, is most probably a place name. However, if it occurs with an honorific title (*Mr.*, *Ms.*, *Dr.*) or with a forename, then it almost certainly names a human individual. If it occurs as subject of the verb *bark*, it most probably names a dog; if it occurs as the subject of the verb *canter*, it is most probably a horse.

Personal names identify human beings individually rather than by group or function. Place names (*see* **Place Names**) perform the same function for locations, while other kinds of proper names include names of businesses, names of pet animals, names of individual works of art, works of literature, films, and other cultural artifacts. It is sometimes supposed that words denoting products are names, but from a linguistic point of view they are more like common nouns, even when spelled with an initial capital letter. English *Mars bar* is a countable noun and denotes a set of entities; *Persil* is a mass noun denoting a mass of soap powder.

Rigid Designators and Individuals

Kripke (1972) argued that a name is a 'rigid designator' that picks out an individual regardless of his, her, or its attributes. For example, if biblical researchers were able to demonstrate that none of the statements made in the Bible about Jonah were true (i.e., he never went on board a ship, was never thrown overboard by his shipmates, was never swallowed by a whale, never went to Nineveh, and never preached the word of God), we would say, 'Oh, we have discovered something new about Jonah,' not 'Oh, he was not Jonah at all, he must be someone else' or 'He was not Jonah, so we must use another name for him.' Following Kripke, several linguistic philosophers, e.g., Putnam (1975a, 1975b), have applied this logic to nouns denoting classes of entities, such as *lemon*, *tiger*, and *water*. However, the question of the extension of rigid designators from individuals to classes is not uncontroversial, and anyway, it is beyond the scope of this article.

The Lexical Status of Personal Names

It is a commonplace that from a synchronic point of view, proper names have no meaning. The etymological meanings of *Patrick* 'nobleman', *Johnson* 'son of John', and *Bradford* 'the broad ford' are simply irrelevant from the point of view of the use of these words in ordinary contexts. These are historical matters, discussed separately in the articles on personal names and place names. Proper names of all kinds (**Personal Names**, **Place Names**, business names, product names) have reference but no semantics. They are the means by which speakers of a language identify individuals and anchor their language (as a system) to the physical and conceptual universe in which they live. Indeed, the facility to say something about individuals may be regarded as a design feature of language.

Certain names, e.g., *Shakespeare*, *Einstein*, *IBM*, *Whitehall*, have a role in the culture to which

speakers of a language collectively subscribe. To be a speaker of English and not know who Shakespeare was is to be a speaker of an extremely impoverished version of it. As a matter of fact, *Shakespeare* is quite a common surname in the West Midlands of England, but from the point of view of users of English as a whole, only one Shakespeare is relevant as a cultural reference point. In other cases, more precise identification is found to be desirable, so that for example the poet *Matthew Arnold* (1822–1888) is regularly referred to by both given name and surname, distinguishing him from other important Arnolds, such as his father, the educationist *Thomas Arnold*, or the 20th-century composer *Malcolm Arnold*.

The traditional distinction between words and names has been responsible for some confusion in the selection of entries for those dictionaries that have a policy of omitting names but including words, with occasionally bizarre results – for example, the definition of *Christ* as an interjection (a word) with no mention of the founder of the Christian religion (a name). Many modern dictionaries reject the semantically based distinction between words and names as a principle for the selection of entries, and take the view instead that the lexicon is a 'cultural system of reference' (Mathiot, 1973) and that therefore a dictionary should aim to be a collective cultural index to a language. This principle implies that a dictionary should include names as well as words, insofar as the former are part of the common knowledge of users of the language.

Vocative and Referential Uses of Names

Different classes of proper names are used in different ways. Names of people and names of domestic animals have two primary functions, *vocative* (when used without syntax, e.g., 'John!') and *referential* (when used with syntax, e.g., 'John said nothing'). The vocative is normally reserved for entities that have cognition, i.e., people and pets. Place names and business names have only *referential* functions. (However, there are exceptions – for example, an artifact may be apostrophized with a vocative, as in Wordsworth's poem beginning "Spade! With which Wilkinson hath tilled his lands . . . .")

The referential function is sometimes loosely described as deictic, but Anderson (2003), describing the grammatical status of proper names within notional grammar (Anderson, 1997), commented that names should not be classified as deictics. He argued that proper names are "nondeictic sources of primary identification." In this system, names are assigned, within a notionally based universal system of syntactic categories, to the category DETERMINATIVE, along with pronouns and determiners. Unlike pronouns and determiners, however, names are "inherently neither definite nor indefinite, nor are they interpreted as nonspecific."

A name cannot be used to predicate something about someone or something. Names do not denote properties. 'She is Jane' identifies an individual; it does not predicate anything about that individual. Apparent exceptions, for example (1), (2), and (3), are not uses of names as identifiers in the normal way but rather transferred uses of names to invoke a category (wise men, resolute women, scientific geniuses, as the case may be) by mentioning a stereotypical member of it, one that has the most salient characteristics of the category.

(1) He is a veritable Solomon.

(2) She is a bit of a Maggie Thatcher.

(3) He is no Einstein.

The determiners and modifiers used in these contexts signal that the names stand for a category rather than an individual.

Syntagmatics of Proper Names

The syntagmatic aspects of proper name usage are largely language-specific. In English, many kinds of proper names (in contrast with *common nouns*) are distinguished by such features as an initial capital letter, use without a determiner, and other syntagmatic features, but these differ according to what kind of entity the name refers to (see Algeo, 1973). Sørensen (1958, 1963) proposed a more extensive inventory of syntactic tests—use with modifiers, use with determiners, conditions under which pluralization is possible, relationship to personal pronouns, etc.—but unfortunately his study, like that of Algeo, was limited to English.

Language-specific differences may be illustrated by just a few of the different uses of the definite article with personal names in different languages. In Greek, but not in English or Italian, a determiner is used before a personal name in all normal referential contexts. In French, but not in English, a determiner is normally used if an adjective is interposed (*le petit Jean*, as opposed to *John*). In German, a determiner before a personal name in a referential context (e.g., *der Franz*, as opposed to *Franz*) is optional; when used, it typically signals informality in register. In English, French, and German (among other languages), names of cities, mountains, lakes, and certain other kinds of locations are used without a determiner, while names of rivers, oceans, and seas are used with the definite article.

Languages differ as to the ways in which a human being is addressed or referred to. These differences are a matter of cultural conventions governed by linguistic norms. Different levels of formality in name use, ranging from hypocoristics (pet forms such as *Bill*) to a person's full name, complete with honorifics, parallel register differences in the wider vocabulary. A study of the pragmatics of register differences in names and titles, with examples chosen mainly from English, Polish, and Russian personal names, can be found in Wierzbicka (1992).

Protocols of Personal Names

In most societies nowadays, personal names consist of two basis elements: a given name chosen at or soon after birth for a child and a second name, the surname or family name, which the child inherits automatically, indicating his or her parentage, family, or clan membership. This two-name structure is now the norm in most societies throughout the world. In many places, older systems are adapting themselves to it; so, for example, an Arabic patronymic or locative name, or a Pakistani honorific such as Begum 'honored lady', may be treated as if it were a Western surname.

A number of variations, exceptions, and additional forms are found, even within societies that use the standard binomial system of personal names. For example, in Europe, as a child grows into adulthood and joins the mainstream of society, any of a variety of hypocoristics (pet forms) may be bestowed on him or her by his or her parents, friends, or schoolmates (*see* **Nicknames**). Subsequently, at the other end of the formality scale, honorifics are acquired in the course of progress through life and education or inheritance (*Mr.*, *Ms.*, *Dr.*, *Sir*). These are normally used with the family name alone (e.g., *Mr. Kelly*, *Herr Schmidt*), but in occasional formal or facetious contexts, they are used with the given name(s) as well (e.g., *Mr. Timothy Patrick Kelly*). There are also variations on conventional nomenclature. In close-knit small communities, for example in rural Ireland, a local doctor may be known as '*Dr. Pat*', coupling an honorific with a hypocoristic form of the given name, while in Britain, at least until about two decades ago, directors of a family firm whose directors all shared the same surname would be known by a combination of an honorific and the given name, e.g., '*Mr. Walter*', '*Mr. Ian*', '*Sir William*'. In French, appellatives can be formed by combining an honorific with a term denoting profession or status, governed by the definite article (e.g., *Monsieur le Maire*, *Madame la Présidente*). In German, the honorific *Doktor* (*Dr.*) is regarded as part of a person's name, and an academic who has acquired not one but two degrees of doctor of philosophy may be known by both of them, e.g., *Herr Professor Dr. Dr. Klein*. Each language and subgroup has its own complex set of protocols governing name use. Different levels of formality are equivalent to different registers in word use.

In some societies, remarkably arcane protocols govern the use of personal names and honorifics among a very small social group (typically, an aristocracy). For example, in England an individual may bear the official name *Percy Wyndham Fotheringay, Earl of Swadlincote* and be known to his friends as *Pooh*. (The example is fictitious, illustrating general principles rather than mentioning a particular individual.) *John, Lord Russell* is to be distinguished in terms of status from *Lord John Russell*. The former would be a lord in his own right, with the 'honor' of Russell, while the latter bears *Lord* only as a courtesy title, because his father is an earl. The official name of such an individual may change dramatically in middle life on the death of a parent or other honor-holding relative, as when the *Marquis of Tavistock* suddenly becomes the *Duke of Bedford* on the death of his father, the previous holder of the superior honor. Some aristocrats bear many honors, depending on the accidents of patronage, heredity, and history. A single individual may be a prince, a duke, a viscount, an earl, and a baron, all rolled into one. The protocols are governed by heraldic officers at the Colleges of Arms in England, Scotland, and Ireland. They date back to the Middle Ages, are associated with colorful pageantry and heraldic symbolism, and are gradually disappearing in today's meritocratic and egalitarian society.

Proper Names: Philosophical Aspects

M Reimer, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

What Are Proper Names?

Intuitively, we can think of proper names as linguistic 'tags.' In the terminology of John Stuart Mill (1843), although proper names denote, they do not connote; they do not 'imply attributes.' For instance, when a speaker uses the name 'Kripke' to refer to the famous philosopher, he or she does not thereby imply anything about Kripke; he or she simply refers to the man. This intuitive construal of proper names is helpful insofar as it provides a rough idea of what philosophers are theorizing about when they claim to be theorizing about 'proper names.' Nevertheless, Mill's characterization is not uncontroversial for reasons discussed later.

Two Central Issues: Meaning and Reference

Proper names raise two central philosophical questions. First, what is the meaning of a proper name? What (in other words) is its contribution to the meanings of the sentences in which it occurs? 'Vienna' presumably contributes something to the meaning of 'Vienna has great pastries.' What exactly does it contribute? Second, how does a proper name refer? How (in other words) does it 'attach to' its bearer? When I say that 'Rumsfeld is in the news again,' the subject term of the sentence I utter 'picks out' a certain Donald Rumsfeld, thereby enabling me to talk about him. What makes this possible? Some philosophers (including Frege, 1892/1962) believe that an answer to the first question will yield an answer to the second. Let us therefore begin with the first question.

Theories of Meaning

Since the rise of analytic philosophy in the early decades of the 20th century, two theories of meaning have dominated the literature on proper names: Millian and description theories. Description theories are motivated largely by their ability to handle the very sorts of cases that prove problematic for Millian theories. Let us therefore begin with the latter.

Millian Theories

According to Millian theories, the meaning of a name is simply its bearer. In other words, a name contributes its bearer (and only its bearer) to the meaning of any sentence in which it occurs. Thus, Vienna itself is what 'Vienna' contributes to the meaning of 'Vienna has great pastries.' Such theories are called 'Millian' after John Stuart Mill, who (as noted previously) famously claimed that proper names denote but do not connote. Thus, insofar as such expressions can be said to 'mean' anything at all, they mean what they denote.

Contemporary Millians, and philosophers of language generally, often prefer to talk in terms of the 'proposition expressed,' where this is understood as meaning (roughly) what is said by the literal utterance of a sentence. Thus, 'Vienna' is said to contribute Vienna itself to the proposition expressed by any sentence in which that name occurs. Vienna is said to be the 'semantic value' of the name. In this way, Millians can avoid the odd-sounding claim that names 'mean' what they refer to. Names do not 'imply attributes'; they do not 'connote.' In that sense of meaning, names do not mean anything at all. Their semantic function is simply to denote and their denotations are what they contribute to the proposition expressed. Recent advocates of Millianism, both of whom talk in this vein, include Nathan Salmon (1986) and Scott Soames (1987).

Proper Names: Philosophical Aspects

M Reimer, University of Arizona, Tucson, AZ, USA

What Are Proper Names?

Intuitively, we can think of proper names as linguistic 'tags.' In the terminology of John Stuart Mill (1843), although proper names denote, they do not connote; they do not 'imply attributes.' For instance, when a speaker uses the name 'Kripke' to refer to the famous philosopher, he or she does not thereby imply anything about Kripke; he or she simply refers to the man. This intuitive construal of proper names is helpful insofar as it provides a rough idea of what philosophers are theorizing about when they claim to be theorizing about 'proper names.' Nevertheless, Mill's characterization is not uncontroversial for reasons discussed later.

Two Central Issues: Meaning and Reference

Proper names raise two central philosophical questions. First, what is the meaning of a proper name? What (in other words) is its contribution to the meanings of the sentences in which it occurs? 'Vienna' presumably contributes something to the meaning of 'Vienna has great pastries.' What exactly does it contribute? Second, how does a proper name refer? How (in other words) does it 'attach to' its bearer? When I say that 'Rumsfeld is in the news again,' the subject term of the sentence I utter 'picks out' a certain Donald Rumsfeld, thereby enabling me to talk about him. What makes this possible? Some philosophers (including Frege, 1892/1962) believe that an answer to the first question will yield an answer to the second. Let us therefore begin with the first question.

Theories of Meaning

Since the rise of analytic philosophy in the early decades of the 20th century, two theories of meaning have dominated the literature on proper names: Millian and description theories. Description theories are motivated largely by their ability to handle the very sorts of cases that prove problematic for Millian theories. Let us therefore begin with the latter.

Millian Theories

According to Millian theories, the meaning of a name is simply its bearer. In other words, a name contributes its bearer (and only its bearer) to the meaning of any sentence in which it occurs. Thus, Vienna itself is what 'Vienna' contributes to the meaning of 'Vienna has great pastries.' Such theories are called 'Millian' after John Stuart Mill, who (as noted previously) famously claimed that proper names denote but do not connote. Thus, insofar as such expressions can be said to 'mean' anything at all, they mean what they denote.

Contemporary Millians, and philosophers of language generally, often prefer to talk in terms of the 'proposition expressed,' where this is understood as meaning (roughly) what is said by the literal utterance of a sentence. Thus, 'Vienna' is said to contribute Vienna itself to the proposition expressed by any sentence in which that name occurs. Vienna is said to be the 'semantic value' of the name. In this way, Millians can avoid the odd-sounding claim that names 'mean' what they refer to. Names do not 'imply attributes'; they do not 'connote.' In that sense of meaning, names do not mean anything at all. Their semantic function is simply to denote and their denotations are what they contribute to the proposition expressed. Recent advocates of Millianism, both of whom talk in this vein, include Nathan Salmon (1986) and Scott Soames (1987).

A central virtue of Millianism is its intuitive plausibility. Intuitively, 'Dick Cheney' refers to Dick Cheney without thereby characterizing him in any way. This taglike feature of proper names appears to be what distinguishes such expressions from much of the rest of meaningful language. Ask someone what 'Tucson' means and you might well get a puzzled look followed by (something like) "It doesn't really 'mean' anything, it's the name of a city in Arizona!" In contrast, you might well get a response to a question about the meaning of 'city.' It means (you might be told) something like 'metropolitan area.'

The central objections to Millianism concern special cases that the theory seems unable to accommodate: cases involving identity sentences, propositional attitude attributions, and 'empty' names (names without bearers). These are the very same cases that provide the central motivation for description theories.

Description Theories

Description theories (associated with Frege, Russell, and, more recently, Searle) claim that the meaning of a proper name is the descriptive or (more generally) conceptual content with which it is associated. For Frege (1892/1962), this associated content (which he called 'sense') is the 'mode of presentation' of the object referred to by the name. It represents the speaker's 'take' or perspective on the name's referent. For others (e.g., Russell, 1912/1917) the associated content is said to be a matter of what the speaker 'has in mind' when using a name. Description theorists sometimes talk as though associated content can be captured via a single description, one shared by members of the linguistic community at large (Russell, 1905, 1919). Yet both Frege (1892/1962) and Russell (1912/1917) acknowledged that the associated content could vary from speaker to speaker. For Russell (1912/1917), and perhaps for Frege as well, such content could even vary for an individual speaker over time. According to contemporary descriptivist Searle (1958, 1983), to the extent that the sense of a proper name can be captured linguistically, it is captured by a 'cluster' of descriptions the individual speaker associates with the name.

The virtues of description theories have been much touted in the philosophical literature. Specifically, such accounts appear to solve a variety of puzzles that can be illustrated by the following sentences:

(1) Hesperus is Phosphorus.

(2) Alice believes that Samuel Langhorne Clemens has a funny middle name.

(3) Sherlock Holmes lives on Baker Street.

(4) Santa Claus does not exist.

Sentences such as (1) are known as 'identity sentences,' sentences such as (2) are known as 'propositional attitude attributions' (because they attribute an attitude, such as belief or doubt, to an agent). Sentences (3) and (4) contain 'empty' names, and the latter is known as a 'negative existential' because it denies the existence of something.

Sentences such as these are puzzling on the assumption that Millianism is true. Suppose the meaning of a proper name is simply its bearer. Then (1), if true, is trivially true, and (2) is synonymous with (5):

(5) Alice believes that Mark Twain has a funny middle name.

Whereas (3) is meaningless (due to a subject term without a bearer), (4) is nearly contradictory: If the subject term is meaningful (if it has a bearer), the sentence is false. Intuitively, however, all of this is mistaken. (1) is both true and informative, and (2) and (5) are not synonymous because the former might be true while the latter is false. (3) is meaningful and (4) is not only meaningful but also true. How can this be? Suppose we construe the meaning of a proper name as the descriptive content with which it is associated. Then proper names are, in effect, descriptions. Consistent with this general picture, let us adopt the following stipulations: 'Hesperus' means 'the brightest star in the evening sky,' 'Phosphorus' means 'the brightest star in the morning sky,' 'Samuel Langhorne Clemens' means 'my eccentric neighbor Sam,' 'Sherlock Holmes' means 'the famous London detective featured in the Conan Doyle stories,' and 'Santa Claus' means 'the jolly bearer of Christmas gifts who lives at the North Pole.' Given these assumptions, we can explain the informativeness of (1), the fact that (2) and (5) mean different things, the meaningfulness of (3), and the truth of (4). To see this, one need only substitute for the proper name the description that captures the name's associated content (e.g., 'The brightest star in the evening sky is the brightest star in the morning sky'). The resultant sentences arguably have the same meaning properties as the original sentences – a fact that lends credence to descriptive accounts of proper names. (For details, see Frege (1892/1962) and Russell (1905), the latter of which contains Russell's analysis of the sorts of sentences that result when a proper name is replaced with a definite description.)

Contemporary Millians (including Salmon, 1986) are not impressed by the description theorist's analysis of sentences such as (1)–(5) and have responded that their own theories can easily account for the intuitive data. The basic idea is to claim that the intuitions surrounding such sentences are the result of mistaking what a speaker might communicate by

their utterance with what the sentences themselves literally express (which is just as Millianism claims). Moreover, description theories of meaning are not problem-free. For instance, if a name '*N*' means what some description 'the *F*' means, then why doesn't '*N* is the *F*' (e.g., 'Cheney is the current U.S. vice president') sound as trivial (in 2004) as 'bachelors are unmarried'? (For this and other problems, see Devitt and Sterelny, 1999.)

Theories of Reference

Some philosophers have thought that description theories of meaning can be extended to account for reference. These philosophers advocate description theories of reference, the *locus classicus* of which is Frege's (1892/1962) 'On sense and reference.' Such theories are no longer as popular as they once were. Since the 1970's, causal theories of reference have provided an attractive alternative to description theories. The causal theory (as originally sketched by Kripke in a series of lectures later published as *Naming and necessity* (Kripke, 1980)) arose in large part out of dissatisfaction with description theories. Let us therefore begin with description theories of reference.

Description Theories

According to any such theory, the referent of a proper name is determined by the descriptive content with which it is associated; in other words, the referent is whatever 'satisfies' the associated content. According to some philosophers (Russell, 1905, 1919), the descriptive content can generally be captured linguistically; others (Searle, 1983) disagree. (Here, differences between versions of description theories of meaning are mirrored.)

The motivation for description theories is both intuitive and methodological. Ask a speaker to what he or she is referring when he or she uses a particular name and the speaker will likely provide a description in response. Ask me to what I am referring when I talk of 'Mount Everest' and I might well respond with an appropriate description, such as 'the tallest mountain in the world.' Such intuitive considerations at least suggest that a proper name (as used by a speaker) refers to its bearer in virtue of that entity's satisfying some descriptive criterion associated with the name. The theory also has a clear methodological virtue when coupled with a description theory of meaning. In this way, a single phenomenon (associated conceptual content) explains both meaning and reference.

The central objections to the theory include the following two, both from Kripke (1980). First, a name can refer uniquely to its bearer even if the associated descriptive content is satisfied by more than one object/individual. 'Cicero' refers uniquely to the famous Roman orator also known as 'Tully' even if the associated descriptive content is simply 'a Roman orator.' This suggests that something more than (or other than) associated descriptive content is needed to determine reference. Second, a name can refer to its bearer even if the associated descriptive content is uniquely satisfied by some other object/individual. 'Einstein' refers to the famous German physicist even if the associated descriptive content (e.g., 'the inventor of the atomic bomb') describes someone else (Oppenheimer). This suggests that something other than descriptive content determines reference. (For further objections to the description theory, see Devitt and Sterelny, 1999.)

Many philosophers (but not all, including Searle, 1983) have viewed Kripke's objections to description theories of reference as decisive. As a result, other theories have been developed, including, most notably, causal theories of reference, the first of which was sketched in Kripke's (1980) *Naming and necessity.*

Causal Theories

A causal theory of reference claims that the link between a name and its bearer is (at least generally) causal in nature. Following Devitt and Sterelny (1999), one can think of such theories as (ideally) having two components: a theory of reference 'fixing' and a theory of reference 'borrowing.' The former explains how a name first gets attached to a certain entity; the latter explains how members of the linguistic community at large are subsequently able to use the name to refer to that entity. So construed, causal theories are easily illustrated. My daughter has a Chihuahua named 'Cocoa.' When she first brought him home, she decided to call him 'Cocoa' because of his chocolate color. She proceeded to call him 'Cocoa,' and Cocoa he thereby became. Reference was accordingly 'fixed' and all those present at the initial applications of the name thereby acquired the ability to use the name. The ability was acquired in virtue of having perceived (and thus been causally affected by) these initial applications. My daughter subsequently told her friends about her Chihuahua (using his name to do so) and thereby enabled those same friends to refer to him via 'Cocoa.' In this way, the causal (perceptual) chain of communication, originating in the initial applications of the name, is extended. My daughter's friends can extend the chain further, enabling still others to refer to Cocoa via 'Cocoa,' simply by using his name in their (attentive) presence. Reference is thereby 'borrowed.'

Although reference is generally causal on this picture, exceptions are acknowledged. It is uncontroversial that there are proper names whose reference is fixed by description. As Kripke (1980) noted, when 'Neptune' was introduced into the language by the astronomer Leverrier, its reference was stipulated to be 'the planetary cause of Uranus's orbital perturbations.' (See Evans, 1979, for a discussion of such 'descriptive' names.)

A central virtue of causal theories is that they avoid the problems of description theories. They claim, in effect, that associated descriptive content is irrelevant to reference. A second (no less important) virtue is that such theories provide a simple and intuitive answer to the question, 'How does language attach to reality?' In a word: causality. (See Devitt and Sterelny, 1999, for details.)

Nevertheless, causal theories are not without their problems. Gareth Evans, in his classic paper 'The causal theory of names' (1973), presented a telling objection to the theory, as originally sketched by Kripke. According to Evans, the causal theory fails to account for the fact of reference change. As Evans pointed out, 'Madagascar' once referred to a portion of the African mainland, but now it refers to the island. Evans argued that the causal theory cannot explain how such changes could occur. (But see Devitt and Sterelny, 1999, for a compelling rejoinder.) In developing an alternative that accounts for reference change, Evans was led to a hybrid theory, one that combines elements from both descriptive and causal theories.

Hybrid Theories

According to Evans's hybrid theory, a name refers to the dominant causal origin of the descriptive information with which it is associated. The intuitive pull of the theory is easily illustrated. Suppose a tattered and centuries-old manuscript is discovered. On its cover is emblazoned the name 'Melford Bibbins.' The manuscript is widely discussed among academics, and its author, known to all as 'Melford Bibbins,' becomes famous for his controversial philosophical views. Intuitively, the individual being referred to is the author of the manuscript, even if it turns out that 'Melford Bibbins' was the name of the scribe to whom the author dictated his work. Evans's theory gets it right: the author of the manuscript is the causal origin of the descriptive information associated with the name and thus the name's referent. The scribe is not the referent, although he is (by hypothesis) the individual at the origin of a causal chain that began with the introduction of the name 'Melford Bibbins' into the language. It would be a mistake to suppose that reference can be explained here via associated descriptive content. Suppose that such content (*the proponent of such-and-such crazy philosophical views*) misconstrues the author's actual views but coincidentally describes precisely the views of some unknown hermit living somewhere in the Appalachian Mountains. In such a case, the author of the manuscript (the intuitive referent of the name) does not satisfy the associated content. Nevertheless, he is arguably the causal origin of that content insofar as he produced the work that generated it.

Devitt and Sterelny (1999) also advocated a hybrid theory. They claimed that reference fixing, to be successful, must involve a conceptual element. If you see a rock but think it is a tortoise and attempt to dub it 'Slow Poke,' reference fixing fails. They called this the 'qua-problem' and solved it by supposing that in order to fix the reference of a name, the speaker must have an accurate (if general) concept of the intended bearer.

Other Expressions

Philosophers often appeal to other expressions in developing their theories of proper names. They do so for (at least) two reasons: to clarify their theories and to provide methodological motivation for those theories. When a contrast is observed, clarification is generally the motivation. When a similarity is noted, promotion of the theory's generality is often the motivation.

Definite Descriptions

Definite descriptions are expressions of the form 'the *F*,' such as 'the current vice president of the United States.' How do these expressions compare with proper names? Millians generally argue they are importantly different: descriptions refer via satisfaction (or 'denotation'). Names refer directly, not in virtue of associated descriptive content. (For this reason, Millian theories are sometimes referred to as 'direct reference' theories.) Russell, in contrast, argued that proper names are 'disguised' definite descriptions and thus subject to the quantificational rendering provided by his theory of descriptions (1905). Frege (1892/1962) similarly treated definite descriptions as semantically of a piece with proper names, claiming that both sorts of expressions have their reference determined by their associated conceptual content (or 'sense').

Natural Kind Terms

Natural kind terms are terms that refer to kinds of things found in nature – 'water,' 'tiger,' and 'lemon' being stock examples. How do these expressions

compare with proper names? Kripke (1980) suggested that these expressions are much like proper names: their reference is not determined by any associated conceptual content but by causal chains of the sort that link proper names to their bearers. These same ideas were developed by Putnam (1975) and later and in greater detail by Devitt and Sterelny (1999).

What Is a Proper Name?

Proper names are terms for denoting specific individuals or individual groups, with personal names being the most typical. In every society each person has at least one personal name, and in large technological societies, a family name as well.

Proper Names and Proper Nouns

In some languages, e.g., English, some classes of proper names, such as personal given names and certain place names, can be syntactically distinguished from common nouns by the absence of a determiner and plural, such as *Ann Smith* rather than *the Ann Smith*. In other languages, like German, proper names may be preceded by the definite article, as in *die Anna, der Hans* and Spanish *La Señorita Lopez*. Family names in English are often used with the plural and article, such as *the Smiths live here*. Certain classes of place names typically occur with articles, for instance rivers, *he lives near the Mississippi River*. Moreover, even with singular personal names, there are productive rules for treating such expressions as classes as in *I know three Ann Smiths. Which Ann Smith are you talking about?* There are also productive rules for converting proper names referring to specific individuals into common nouns: *Ann Smith is more of a Florence Nightingale than a Marie Curie*.

Personal Name Inventories

Most languages have an inventory of given personal names. In English and other European languages, these items have no meaning. In some case a meaningful etymon might be found, but speakers are not generally aware of this. Names for children are selected according to the parents' preferences, or perhaps a child is named after someone else in the family. However, in some societies, names are taken from the common vocabulary, and that meaning constrains

compare with proper names? Kripke (1980) suggested that these expressions are much like proper names: their reference is not determined by any associated conceptual content but by causal chains of the sort that link proper names to their bearers. These same ideas were developed by Putnam (1975) and later and in greater detail by Devitt and Sterelny (1999).

What Is a Proper Name?

Proper names are terms for denoting specific individuals or individual groups, with personal names being the most typical. In every society each person has at least one personal name, and in large technological societies, a family name as well.

Proper Names and Proper Nouns

In some languages, e.g., English, some classes of proper names, such as personal given names and certain place names, can be syntactically distinguished from common nouns by the absence of a determiner and plural, such as *Ann Smith* rather than *the Ann Smith*. In other languages, like German, proper names may be preceded by the definite article, as in *die Anna, der Hans* and Spanish *La Señorita Lopez*. Family names in English are often used with the plural and article, such as *the Smiths live here*. Certain classes of place names typically occur with articles, for instance rivers, *he lives near the Mississippi River*. Moreover, even with singular personal names, there are productive rules for treating such expressions as classes as in *I know three Ann Smiths. Which Ann Smith are you talking about?* There are also productive rules for converting proper names referring to specific individuals into common nouns: *Ann Smith is more of a Florence Nightingale than a Marie Curie*.

Personal Name Inventories

Most languages have an inventory of given personal names. In English and other European languages, these items have no meaning. In some case a meaningful etymon might be found, but speakers are not generally aware of this. Names for children are selected according to the parents' preferences, or perhaps a child is named after someone else in the family. However, in some societies, names are taken from the common vocabulary, and that meaning constrains

the name use. For example, in Japanese *Kazuhiko*, meaning 'firstborn,' is a possible name for the first-born son. Among the Akan of Ghana, children are given names based on the day of the week of their birth (Boadi, 1984). *Kofi,* 'born on Friday,' is an example, as Kofi Annan was born Friday, April 8, 1938. Among the Gengbe, also know as Mina, spoken in southern Togo, there is a specific name for each son and daughter born to a woman, based on birth order. For example, *Poovi* is the name given to the fifth daughter.

Gender-Specific Names

Most names are gender specific. Tanz has identified three common patterns: (a) names may be gender specific and phonologically unrelated to a corresponding name of the other gender, such as *Thomas* or *Susan.* (b) A masculine name can serve as a stem to which feminine suffixes can be added; from *Paul* can be formed *Paula, Paulette,* and *Pauline*. Often the feminine suffix occurs on common nouns as well, as French *-ette* or Japanese *-ko*, meaning 'little.' (c) A name can be formed from a neutral stem to which both masculine and feminine suffixes are added, as in Latin, where feminine *-a* and masculine *-us* could be added to most name stems, for example, *Claudia, Claudius,* and *Julia, Julius*. The fourth potential pattern of adding a masculine suffix to a feminine name, e.g., **Susanus,* does not occur. Sometimes the gender specificity of a name may shift, but the direction is from masculine to feminine. *Shirley* was formerly a man's name but is now a woman's name.

In some languages, e.g., Chinese, personal given names are taken from the common vocabulary, and gender specificity can be found here as well, with boys' names taken from words with meanings of strength and courage and girls' names taken from words for beauty and gracefulness (Tanz, 1982).

Change in Name Popularity

Lieberson (2000) examined the changing fashions in first names given to girls and boys in the United States and in Britain, and other European countries. Until the end of the 19th century, naming customs were stable, and there was little change in the names given to infants or to the naming principles, such as naming the oldest son after the father. Then new names started to appear among the most popular names, and this trend accelerated. Lieberson found that *Mary* was among the top 10 most popular girls' names from 1906 through 1969 and was the most popular name for 27 of those years in California, but it is no longer popular. *Jennifer* did not appear in the top 100 names until 1952, appeared in the top 20 in 1965, and from 1970–1982 was the most popular name for girls; it still remains popular. *Kelly*, however, was in the top 20 only from 1970 until 1975.

Boys' names are more conservative. *John, James, Michael, David, Robert*, and *William* have remained in the top 10 during the 20th century in California. Yet there has been considerable change in naming boys as well. *Eric* and *Jeffrey* were in the top 20 first in 1965, but dropped out by 1980.

Nicknames

One subclass of personal names is nicknames, and in English there are three primary principles of nicknaming. First of all, a nickname can be constructed from the common vocabulary where a word selected is appropriate for the specific individual. For example, a person with red hair might have *Red* as a nickname, or a short person might be called *Shorty.* Nicknames are often used ironically, however, so *Shorty* might be given to a very tall person. In Australia, *Blue* is a common nickname for red-headed males. The second nicknaming principle is a conventional relationship between names and nicknames, though this relationship is many-many rather than one-one. Conventional nicknames for *Elizabeth* are *Betty, Bess*, and *Liz*; for *Robert* they are *Bob, Rob, Bobby,* and even *Bert*. However, *Bobby* is also a nickname for *Roberta* and *Barbara*. The line between formal given names and nicknames is obscured because many nicknames are used as legal names. In the southern U.S. states it is common to name boys *Jimmy* or *Bobby.* The third principle, which overlaps with the second, is to add the diminutive suffix *-y* or *-ie* to the name or to part of the name: *Annie, Maddy,* and *Keithy* are nicknames for *Ann, Madeleine* and *Keith* respectively.

Personal Names for Roles

Some names function as generics, often as vocatives. Examples are *George* for a railway porter in a sleeping car in American English, *Maria* for a female street peddler in Mexico, and *Mack* in addressing a stranger (e.g., *Hey, Mack, you forgot your card*). Generic names are also used to make general reference more concrete, as in *She'll go out with any Tom, Dick, or Harry who asks her.* Names like *John Doe* and *Jane Doe* are used in court cases in the United States to protect the identities of those involved.

Proper Names That Shift to Common Nouns

The shift from proper nouns to common nouns is not unusual, especially where the common noun denotes something associated with the name, for example, something invented by that person (*shrapnel,*

sandwich), or named in honor of someone, like the bakery products *bismark* and *napoleon*. This shift is productive. One can call someone a *Rembrandt*, a *Shakespeare*, or a *Beethoven* to imply that he or she is a great artist, writer, or composer, presumably in any style. However to call someone a *Picasso* or a *Schoenberg* is likely to suggest an artist or composer of a particular style, e.g., cubist art and atonal music.

Names for Things Other Than Persons

Although the most salient things that receive proper names are individual people and places, other things are named as well, generally individual creatures and objects that are identifiable and important. Included in this category are domestic animals, especially pets; important architectural objects like large buildings, bridges, and highways, and in some places, houses; swords (in heroic epics), important events such as wars, and important weather phenomena like hurricanes. Many of these things are named by words and phrases taken from the common vocabulary, but they are proper names, nevertheless. Alternative expressions that might be equally appropriate are not the correct names. For example, the *Franco-Prussian War* and the *War of 1812* could have been called the *War of 1870* and the *Franco-English War*, but these latter names are wrong. In each of these domains there are conventions or at least patterns of naming, which vary across cultures (see Carroll, 1985).

Animal Names

Names for cats and dogs tend to be single words, compared to names for racehorses, which tend to have two or three names. Cat and dog names are commonly drawn from the stock of human first names (e.g., *Fred*), from descriptions (*Fluffy, Smoky*), or after famous people (*Cleopatra, Plato*). Names with ethnic associates are found for breeds from specific places. A German shepherd might be called *Hans* and a Russian wolfhound *Boris* (see Taggart, 1962). There is a small inventory of dog names: *Spot, Rover, Fido*, which are found in cartoons. Racehorses have names that connote speed and winnings, such as *Lucky, Lucky, Lucky* or *Winning Streak*.

Names for Rock Bands

Names of rock groups are often unconventional, sometimes even outrageous and offensive. A large class of names deal with death, such as the *Grateful Dead, The Dead Kennedys, Overkill, Slayer, Suicidal Tendencies*, *Death Cab for Cutie*, and the *Trail of Dead*. Other common categories are drugs (*Pot Leaf, Alcoholica),* dangerous animals (*King Cobra, Scorpions*) weapons (*U–2),* abnormality (*Misfits, Atrophy*, *Brain Damage* and *Disturbed*) and a variety of other negative and/or weird names, like *Widespread Panic, the New Pornographers*, *Puddle of Mudd*, and the *Goo Goo Dolls.*

Street Names

Street names follow patterns that vary from country to country. In the United States streets are typically named after famous people, geographical features, trees, presidents, places (cities, states, and islands), numbers and letters. They are not named after dates for important events, however, a practice that is common in Mexico. When numbers or letters are used, they conform to numerical order (of whole positive integers) and the order of the alphabet.

Brand Names

Brand names are often considered to be a subclass of proper names because they are written with capital letters, but syntactically they act like common nouns: for example, *He used to buy only Buicks, but now he has a Chevrolet*. Semantically, they do not refer to unique individuals but to classes of objects or to mass substances. However, brand names are like proper names in that they are consciously and carefully selected, and moreover, unlike personal names, they can be copyrighted so that no one else can use them. Names for automobile makes and models provide an interesting domain. In the United States popular sources for cars are names for animals associated with strength, speed, and grace (*Cougar, Lark, Falcon*), attractive places, especially resort areas (*Biarritz, Riviera, Monte Carlo*), astronomical objects (*Comet, Pulsar, Galaxy, Mercury*), meteorological objects (*Tempest, Cyclone, Duster*), and racetracks (*Grand Prix, Le Mans, Daytona, Sebring*).

Brand names are one of the few areas of the vocabulary where words are coined from scratch, and names like *Xerox*, based on Greek *xeros* (ξηός) 'dry' (copying) and *Kodak* with eye-catching spelling appear. Firms are also careful to select appropriate sounding names, drawing on principles of sound symbolism (Bolinger, 1980).

Alternative Names

Actors and singers sometimes take stage names (Lieberson, 2000: 6):

Stage names	Original Name
Woody Allen	Allen Konigsberg
Fred Astaire	Frederick Austerlitz
Tony Bennett	Anthony Benedotto

Victor Borge	Borge Rosenbaum
Joan Crawford	Lucille LeSueur
Doris Day	Doris van Kappelhoff

Often stage names were used to avoid the prejudice connected with the ethnicity of the original names or to make the stage name sound more attractive or maybe just shorter. Virginia Patterson Hensley took the stage name Patsy Cline. Alice Cooper (originally Vincent Furnier) chose an inappropriate name (genderwise), but heavy metal rock bands, like their names, are often deliberately unconventional. Many performers go by only one name: Cher, Madonna, Prince, Ann-Margaret, Hildagard.

Writers like George Eliot and Georges Sand presumably chose masculine *noms de plume* to avoid the prejudice against women writers of their time.

Place names may be changed for political reasons. St. Petersburg, Russia, was renamed Leningrad in 1924 and then returned to its earlier name in 1991 after radical political changes. The central African country and river called the Congo were renamed Zaire from 1971 under the dictatorship of Mobutu Sese Seko, but the earlier name was restored after he was ousted from power in 1997.

Cognates and Translations

Given names of name inventories in various languages have cognates, names whose phonology differs because of independent sound changes in the different languages. Latin *Petrus* became *Peter* /ˈpiˈtə/ or /ˈpiˈtɚ/ in English, *Pedro* /ˈpɛdro/ in Spanish, and Pierre /pjɛˈʁ/ in French. Place names, too, are different because of sound change. English *Vienna* and *Paris* are *Wien* /vijn/ in German and /paˈʁi/ in French, respectively.

Different languages/cultures have different traditions in translating names. The U.S. president's residence, the *White House*, is translated into French as *La Maison Blanche* and German as *Weisshaus*. But in Japanese, it is only transliterated into Japanese orthography. In English, Chinese place names like *Forbidden City* and *Temple of Heaven* are translated, whereas *Tiananmen* meaning 'heavenly peace' remains *Tiananmen Square*.

Movie titles are not necessarily translated, and when they are, translations are not always literal. The German film *Der Krieger und die Kaiserin* was translated into English as *The Warrior and the Princess*, although *empress* is the standard equivalent of *Kaiserin*. At other times completely different titles are chosen, which although related to the movie, are unrelated to the original title. The American film *Truth and Dare*, for example, appeared in Austria as *In Bett mit Madonna*, while *Calamity Jane* has the French title *La Blonde du Far West*.

Philosophical Aspects of Names

Philosophers of language have been especially interested two questions: (1) What is the meaning of a proper name? and (2) What is the mechanism by which a proper name refers? With respect to (1), some philosophers deny that names have any sense, whereas other claim that the meaning of a name is what it refers to. As for (2), there are two well-known approaches: the causal theory and the description theory. The causal theory (Kripke, 1980; Devitt, 1981) says that a name refers to its bearer by virtue of a causal chain of communication that originates typically in a perceptual dubbing of an individual or object, exceptions being nonexistent names like *Minerva* or *Sherlock Holmes*). The descriptive theory (Russell, 1905; Searle, 1960) links names with descriptions, but not necessarily with any unique description. There are also hybrid theories.

Recanati's position draws on the virtues of both positions. Although he basically takes the nondescriptive position, he says that when an object is known only by its description, as say *Jack the Ripper*, we may anticipate that that the object will come to be known in a more direct manner (1993: 183). Proper names in thought or in encyclopedia entries, however, may indeed be presented descriptively, but there is no unique or constant mode of presentation.

The causal theory works best for naming people we know or know of and can identify, such as Martin Luther King, for whom we can imagine an entirely different history. The descriptive theory is most suitable when the referent has not been identified, or for names and individuals whose existence has been questioned, such as Homer or Moses. The descriptive theory is also appropriate for fictional characters in art and literature (*see* **Proper Names: Philosophical Aspects**).

Once one moves beyond personal names and looks at names for products, businesses, and organizations, then the meaning of the words used in the names becomes relevant. In such cases, the appropriateness of the name is constrained by the meaning.

Prophecy

D Petersen, Emory University, Atlanta, GA, USA

© 2006 Elsevier Ltd. All rights reserved.

Prophets have been known by many titles (e.g., *shaman* [Tungus], *nābîʾ* [Hebrew], *muḫḫû* (Akkadian), *prophētēs* [Greek]) and in diverse cultures, both ancient and modern. These religious figures who speak or act on behalf of a deity have often been distinguished from other types of intermediaries (e.g., priests or diviners), though such distinctions often blur. Prophets functioned at various places in a society. They could address both governmental and religious officials as well as private individuals. Moreover, they could function at either the center or the periphery of a society.

The behavior of prophets could result in the creation of literature (oral and/or written), the most well known of which is preserved in the Hebrew Bible. Other important exemplars derive from ancient Mesopotamia (both the Old Babylonian and Neo-Assyrian periods). Such literature may stem either from the hand of the prophet or from another person, sometimes an epigone. Literature reflecting the activity of prophets occurs in both prose and poetry. Important biblical examples of the former include the divination chronicle (Zech. 1:18–21), vision report (Zech. 1:18–21), biography (Jer. 37–44), legend (2 Kings 4:1–7), symbolic action report (Isa. 20:1–6), commissioning report (Jer. 1:4–10), and prophetic historiography (Isa. 36–39).

Poetic texts are particularly prominent in biblical prophetic literature. They are of two basic types: divine oracle, in which the deity speaks in the first person (e.g., Jer. 8:18–19), and prophetic saying, in which the prophet speaks about the deity in the third person (e.g., Isa. 27:3). Ancient prophets often appropriated forms of discourse from within their societies. Amos apparently knew the language of ancient legal systems and formulated oracles that included both an indictment and judgment. Amos 2:4 charges the audience with religious malfeasance whereupon Amos 2:5 offers a sentence of national destruction. Prophets could also adapt traditional forms of speech in new and ironic ways. Amos 5:1–3 uses the vocabulary and poetic style of a funeral to inveigh against the society of ancient Israel.

Study of prophetic literature has proceeded in diverse ways:

1. Early critical scholarship focused on the question of what portions of biblical prophetic literature constituted the *ipsissima verba* of an individual prophet. Those portions not deemed to be genuine were viewed as of minimal significance. More recently, scholars have analyzed the formation of the literature, recognizing that the final form of prophetic texts reflected the social and religious

Amos 2:4 charges the audience with religious malfeasance whereupon Amos 2:5 offers a sentence of national destruction. Prophets could also adapt traditional forms of speech in new and ironic ways. Amos 5:1–3 uses the vocabulary and poetic style of a funeral to inveigh against the society of ancient Israel.

Study of prophetic literature has proceeded in diverse ways:

1. Early critical scholarship focused on the question of what portions of biblical prophetic literature constituted the *ipsissima verba* of an individual prophet. Those portions not deemed to be genuine were viewed as of minimal significance. More recently, scholars have analyzed the formation of the literature, recognizing that the final form of prophetic texts reflected the social and religious

realities of a later period as well as the conditions in which the utterances were initially spoken.
2. Scholars continue to compare prophetic texts of one culture with those from other settings. For example, recent publication of Akkadian texts attests the preserving of more than one oracle on a clay tablet. Such practice marks the transition from archival preservation of one oracle to the creation of prophetic literature, i.e., the arranged composition of multiple oracles and sayings. Such compositions are observable in both biblical and extrabiblical texts.
3. Study of the rhetorical and literary features of prophetic texts is currently of great interest, particularly as such study has been informed by new understandings of Hebrew poetry.

Propositional and Predicate Logic: Linguistic Aspects

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Logic is defined by two key notions, entailment and calculus. More precisely, a logic is a calculus for the derivation of entailments. Entailment is a relation between assertive sentences or, rather, between propositions expressed by assertive sentences. (Henceforth, the term 'sentence' is used for 'assertive sentence.') Entailment for sentences is defined as follows:

> A sentence or a set of sentences P **entails** a sentence Q (P⊨Q) just in case whenever P is true, Q must of necessity also be true, on account of the meanings of P and Q – that is, for analytical reasons.

There is an immediate complication, however. Strictly speaking, it is not sentences that are true or false but, rather, their utterance tokens and their underlying propositions. It is impossible to say whether the English sentence *Jack arrived late* is true or false as long as the person called *Jack* and the time referred to are not specified. The vast majority of natural language sentences are occasion sentences in the sense that they contain a number of parameters that must be given specific values in the world spoken about before there can be talk of truth or falsity. The values for such parameters in one sentence together we call the 'key' of the sentence in question. Only a properly keyed sentence can function as an utterance token with a truth value. It is true that there are sentences, called 'eternal sentences,' that can do without a specific key, such as *all humans are mortal*. These are to be considered marginal cases whose key is the universe as a whole. Starting with Aristotle, the logical tradition has preferred to avoid the complications caused by the keying condition and has, in principle, developed logics only for eternal sentences. Only recently has there been a greater awareness that such a limitation is not fruitful.

Since the vast majority of sentences are occasion sentences, the entailment relation, when defined for sentences, must be defined *modulo key* – that is, with reference values kept constant. Under this condition it can be said that *Jack has been killed* entails *Jack is dead* because it is in the meaning of the predicate *be killed* that whoever has been killed is of necessity dead. Propositions, by contrast, if taken to be token occurrences of mental acts in which a property is assigned to one or more objects, are keyed by definition and thus do not need the *modulo key* condition. The analyticity condition remains unchallenged: When a proposition P entails a proposition Q, it does so in virtue of the cognitively defined meanings of the predicates in any linguistic expressions of P and Q.

The analyticity condition must be clearly distinguished from other conditions that justify the drawing of a conclusion. For example, *Jack was shot in the heart* does not entail *Jack died* because, even though Jack's death is a direct consequence of his being shot in the heart, this is not a semantic but a physical

realities of a later period as well as the conditions in which the utterances were initially spoken.

Propositional and Predicate Logic: Linguistic Aspects

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Logic is defined by two key notions, entailment and calculus. More precisely, a logic is a calculus for the derivation of entailments. Entailment is a relation between assertive sentences or, rather, between propositions expressed by assertive sentences. (Henceforth, the term 'sentence' is used for 'assertive sentence.') Entailment for sentences is defined as follows:

> A sentence or a set of sentences P **entails** a sentence Q (P⊨Q) just in case whenever P is true, Q must of necessity also be true, on account of the meanings of P and Q – that is, for analytical reasons.

There is an immediate complication, however. Strictly speaking, it is not sentences that are true or false but, rather, their utterance tokens and their underlying propositions. It is impossible to say whether the English sentence *Jack arrived late* is true or false as long as the person called *Jack* and the time referred to are not specified. The vast majority of natural language sentences are occasion sentences in the sense that they contain a number of parameters that must be given specific values in the world spoken about before there can be talk of truth or falsity. The values for such parameters in one sentence together we call the 'key' of the sentence in question. Only a properly keyed sentence can function as an utterance token with a truth value. It is true that there are sentences, called 'eternal sentences,' that can do without a specific key, such as *all humans are mortal*. These are to be considered marginal cases whose key is the universe as a whole. Starting with Aristotle, the logical tradition has preferred to avoid the complications caused by the keying condition and has, in principle, developed logics only for eternal sentences. Only recently has there been a greater awareness that such a limitation is not fruitful.

Since the vast majority of sentences are occasion sentences, the entailment relation, when defined for sentences, must be defined *modulo key* – that is, with reference values kept constant. Under this condition it can be said that *Jack has been killed* entails *Jack is dead* because it is in the meaning of the predicate *be killed* that whoever has been killed is of necessity dead. Propositions, by contrast, if taken to be token occurrences of mental acts in which a property is assigned to one or more objects, are keyed by definition and thus do not need the *modulo key* condition. The analyticity condition remains unchallenged: When a proposition P entails a proposition Q, it does so in virtue of the cognitively defined meanings of the predicates in any linguistic expressions of P and Q.

The analyticity condition must be clearly distinguished from other conditions that justify the drawing of a conclusion. For example, *Jack was shot in the heart* does not entail *Jack died* because, even though Jack's death is a direct consequence of his being shot in the heart, this is not a semantic but a physical

consequence, brought about not by the semantic description of the predicates in question but by physical causation. To be able to draw the corresponding conclusion we need world knowledge, not knowledge of the language.

Most entailments are *intuitive* in that they are based on speakers' knowledge of their language. Some entailments, however, can be made *formal* in that they can be computed with the help of a calculus. When that is the case, we have a logic. Every logical system distinguishes between its logical constants and its variables. In propositional calculus, for example, the logical constants are the words *and*, *or*, *if*, and *not* and the variables range over linguistically expressed propositions. In standard first-order predicate calculus, the logical constants are those of propositional calculus plus the words *all* and *some*, and the variables range over predicates and individuals. The logical constants define the calculus.

The notion of logic was discovered in Plato's Academy, mainly by Aristotle (384–322 B.C.E.), who began as a student and later became a prominent member of the Academy. He discovered that the negation word *not* functions differently according to whether the subject term is or is not quantified. The sentence *Plato does not live in Athens* is true whenever *Plato lives in Athens* is false, and vice versa, the former sentence being equivalent to 'it is not true that Plato lived in Athens.' Here, the negation is full sentential, or external, negation. But in, for example, *some Greeks do not live in Athens,* the negation cannot be external because both this sentence and *some Greeks live in Athens* can be true at the same time. The difference is that in the latter pair of sentences the subject term is quantified, whereas in the former pair it is a referring expression. Apparently, in sentences with a referring expression as subject term it makes no truth-conditional difference whether the negation is external or internal, but in sentences with a quantified subject term it does. This discovery intrigued Aristotle and some of his fellow students. It eventually resulted in what is now known as Aristotelian-Boethian Predicate Calculus (ABPC), a form of predicate logic due in the first place to Aristotle but remodeled (and to some extent spoiled) by later commentators, especially the Roman-Christian philosopher Boethius (ca. 475–524 C.E.).

Predicate Calculus

ABPC, like standard modern logic, is restricted by a few overarching principles. First there is the *Principle of Contradiction*, which says that no sentence can be true and false at the same time. Then comes the *Principle of Bivalence*, which says that every sentence is either true or false, with nothing in between and no further truth values. A further restriction, applying throughout, is the *Principle of Extensionality*, which restricts the applicability of logic to really existing, actual objects, eliminating all virtual objects (*see* **Virtual Objects**), such as Sherlock Holmes or the Golden Mountain, which have been thought up by creative minds.

Table 1 Boethius's sentence types

A: All *F* is *G*	**E**: All *F* is not-*G* ≡ No *F* is *G*
I: Some *F* is *G*	**O**: Some *F* is not-*G* ≡ Not all *F* is *G*

The Principle of Contradiction seems firmly rooted in cognition and language, but the other two principles, although universally accepted nowadays, are open to doubt. Presuppositional phenomena, in particular, strongly suggest that the Bivalence Principle does not fit the facts of language (*see* **Presupposition**). And the Principle of Extensionality is clearly inadmissible in any logico-semantic analysis of human language, which quantifies with equal ease over actual and virtual objects (*see* **Virtual Objects**). This last complication is allowed to rest in the present context.

Under the principles given, the (external) negation *not*, or ¬, is a toggle between truth values: if P is true, ¬P is false, and if ¬P is true, P is false; ¬¬P is equivalent to P (¬¬P ≡ P). P and ¬P are called Contradictories. Given the principles mentioned and the definition of *not* (¬) just given, it follows that when P ⊨ Q, then ¬Q ⊨ ¬P – an entailment schema known as *Contraposition*.

As regards ABPC specifically, Boethius distinguished four sentence types, the types **A** and **I** (from Latin *affirmo* 'I affirm') and **E** and **O** (from Latin *nego*, 'I deny'), defined as in Table 1 (the variables *F* and *G* range over predicates). ABPC is then defined by the following entailment schemata. Sentences of type **A** entail sentences of type **I**, and those of type **E** entail those of type **O**. Formally: **A** ⊨ **I** and **E** ⊨ **O**. These are known as the *subaltern entailments*. Moreover, both **I** and **O** entail 'there is at least one *F* – an entailment known as *existential import*. Given the entailment **A** ⊨ **I**, it follows that **A** and ¬**I** cannot be true simultaneously, although they may be false together: they are *contraries*. Aristotle himself added the entailments from *some F is G* to *not all F is not-G* and from *all F is not-G* to *no F is G* (Kneale and Kneale, 1962: 57). However, his later commentators, especially Boethius, went further and added the converses of these two entailment schemata: from *not all F is not-G* to *some F is G* and from *no F is G* to *all F is not-G,* thereby creating the now standard *conversions* that allow conversion of *all* into *some,* and vice

Figure 1 (A) ABPC and (B) AAPC represented as Squares of Oppositions.

versa, provided both an external and an internal negation are added (or removed). Now *all F is G* and *no F is not-G*, and *some F is G* and *not all F is not-G* are equivalent. With the conversions added, it follows that **I** and **O** cannot be false together, although they can be simultaneously true; they are subcontraries.

ABPC is known in the traditional form (due to Boethius) of the *Square of Oppositions*, shown in Figure 1A. Aristotle's original system, called Aristotelian-Abelardian predicate calculus (AAPC), is shown in Figure 1B (the asterisk stands for internal negation: **A*** is *all F is not-G*; **I*** is *some F is not-G*).

It is important to insist on the difference between ABPC and AAPC because ABPC contains a logical fault that is absent in AAPC. This fault becomes visible when we consider a world (such as ours) without any mermaids. In such a world, the sentence *all mermaids swim* must be either true or false, owing to the Bivalence Principle. If it is true, *some mermaids swim* must also be true (subaltern), from which it follows, contrary to fact, that there are mermaids (existential import). But if it is false, then *not all mermaids swim* is true and entails (by conversion) *some mermaids do not swim*, which likewise entails (by existential import) that there are mermaids, again contrary to fact. Therefore, *all mermaids swim* can be neither true nor false when there are no mermaids, which violates the Bivalence Principle. The problem with ABPC is, thus, that it cannot deal with situations in which the *F*-class is null: only when the *F*-class is nonnull are the subaltern entailments applicable. This goes against the very notion of logic because entailments are valid not in virtue of world contingencies but in virtue of meanings. This logical fault is called *undue existential import* (UEI).

To repair this fault, standard modern predicate calculus (SMPC) was developed by mathematical logicians such as Boole, Frege, Peano, and Russell during the late 19th and early 20th centuries. SMPC is indeed free from this, or any other, logical fault and is now universally accepted as the one and only sound predicate calculus, which must be embodied in human language if that can lay claim to logical soundness. This deeply ingrained belief, however, is unwarranted.

To see what is at issue it is useful to go back into history. That ABPC is logically faulty was not entirely unknown to medieval philosophers. Peter Abelard (1079–1142), in particular, had seen the fault and restored Aristotle's predicate logic to its original form (hence the name AAPC; see Seuren, in preparation). Yet his (and Aristotle's) way of avoiding UEI was never taken up by the logical tradition, which stuck to the faulty Boethian system until the advent of modern logic. Had the tradition been more attentive, it would have seen not only that the Aristotelian-Abelardian system is logically sound but also that it has much greater logical power than SMPC. This question is worth unraveling.

Despite its long tradition, the Square of Oppositions is not a very good way of representing ABPC because it expresses neither the conversions nor the role of internal negation. A better representation is shown in Figure 2A, where the symbols **E** and **O** have been eliminated in favor of external (¬) and internal (*) negation. The analogous representation of AAPC is given in Figure 2B. Figures 2A and 2B show two logically isomorphic triangles, each with the vertices **A**, **I**, and ¬**I**, one with and one without the internal negation. In each triangle, the three logical relations are entailment, contradiction, and contrariety. The figures differ in that Figure 2A has the conversions, whereas Figure 2B has the one-way entailments of AAPC, and AAPC lacks the relation of subcontrariety.

A *valuation space representation* (Van Fraassen, 1971) shows why logical relations hold. The valuation space (VS) /P/ of a sentence P is the set of situations, in the universe of situations **U**, in which P is

Figure 2 Improved representations of (A) ABPC and (B) AAPC.

Figure 3 The VS models for (A) ABPC and (B) AAPC.

true (*modulo* key). Logical relations can be read from VS models:

When /P/ ⊆ /Q/, P ⊨ Q.
When /P/ = /Q/, P ≡ Q.
When /P/ ∩ /Q/ = Ø, P and Q are contraries.
When /P/ ∪ /Q/ = **U**, P and Q are subcontraries.
When /P/ ∩ /Q/ = Ø and /P/ ∪ /Q/ = **U**, P and Q are contradictories.

ABPC is represented in Figure 3A and AAPC in Figure 3B.

ABPC lacks a space for cases in which the extension of the *F*-predicate is null ([[*F*]] = Ø), which makes its applicability dependent on the contingent condition that [[*F*]] ≠ Ø, but AAPC has space 4 for the situations in which [[*F*]] = Ø. In these situations, the four sentence types, **A**, **I**, **A***, and **I*** are all deemed false.

The VSs of the eight sentence types are read from Figure 3 as shown in Table 2. In both systems, the subalterns hold from **A** to **I** because {1} ⊆ {1,2}, and from **A*** to **I*** (or, for AAPC, ¬**A**) because {3} ⊆ {2,3} (or {2,3,4}). But AAPC lacks the subaltern from ¬**I** to **I*** because {3,4} ⊈ {2,3}. The conversions do not hold in AAPC because ¬**I*** ⊭ **A**, as {1,4} ⊈ {1} and ¬**I** ⊭ **A***, as {3,4} ⊈ {3}. The contraries have remained intact in AAPC, except for the pair ¬**I** and ¬**I***, because {3,4} ∩ {1,4} ≠ Ø. Subcontrariety between **I** and **I*** has been lost in AAPC because {1,2} ∪ {2,3} ≠ **U**.

SMPC presents a solution to UEI based on a direct interpretation of *all* as set-theoretic inclusion and of *some* as set-theoretic intersection: *all F is G* is interpreted as [[*F*]] ⊆ [[*G*]], and *some F is G* as [[*F*]] ∩ [[*G*]] ≠ Ø. When [[*F*]] = Ø, *all F is G* is true because the null set Ø is included in any set. **A** and **A*** sentences are thus taken to be true when [[*F*]] = Ø, which allows the conversions to remain intact. This solution, which depends on the interpretation of *all* as inclusion and of *some* as intersection, may be convenient for the logic of mathematics but lacks any linguistic necessity. Given Boolean algebra and standard set theory, we are free to interpret *all* and *some* in different terms. For example, *all* may be defined as yielding truth on condition that [[*F*]] ⊆ [[*G*]] and that [[*F*]] ≠ Ø. This, in fact, appears to correspond more closely to the way the meaning of *all* is defined in natural language than the simple condition that [[*F*]]

$\subseteq [[G]]$, which fits the facts of language badly. The VS model of SMPC is as in Figure 4.

This shows that almost all entailment relations are lost: the subalterns are gone, as are the contraries and subcontraries. All that has remained is the contradictories and the conversion equivalences. This makes SMPC extremely impoverished compared with either ABPC or AAPC.

It also makes SMPC redundant for the use of language because, when $[[F]] = \emptyset$, the truth value of all eight sentence types considered follows automatically from the theorems of standard set theory. This is so because, for any sets X and Y, $X \subseteq Y$ when $X = \emptyset$, and $X \cap Y = \emptyset$ when X or Y or both equal $\emptyset$. When the class of situations where $[[F]] = \emptyset$ is excluded from SMPC, the truth value of the eight sentence types becomes contingent on circumstances, which makes the corresponding sentences informative. Because the logic that results when the situations where $[[F]] = \emptyset$ are eliminated is identical to ABPC, natural language has a functional interest in ABPC. Such an elimination affects only the semantics of *all*: **I** and **I*** sentences are unaffected by the condition that $[[F]] \neq \emptyset$. It follows that if ABPC can be upheld without the logic becoming unsound, the information value of expressions containing the quantifier *all* will be greatly enhanced. The question is whether natural language can manage to maintain ABPC while keeping its logic sound.

In general, if the semantic description of certain words turns out to be such that they allow for a logical calculus, then that calculus is the logic of language. To find out what the logic of language amounts to, we should, therefore, investigate the meanings of possible logical constants and see what calculus results. For predicate calculus, the logic of language is thus defined by the linguistically given lexical meanings of the words *all*, *some,* and *not*.

It seems that language has outsmarted the logicians by making sentences context-sensitive, using the device of presupposition (*see* **Presupposition**), which restricts the informative use of sentences to consistent contexts, in which the presuppositions of the

Figure 4 The VS model for SMPC.

sentences in question are stored as preliminary information. The truth of a sentence co-depends on the truth of its presuppositions as stored in the embedding context. If they are not all true, the sentence is false in a special way, called 'radically falsity,' which implies the falsity of at least part of the embedding context and, hence, the futility of the sentence itself in that context. Radical falsity (F2, written as $\simeq$) constitutes a third truth value in addition to truth (T) and minimal falsity (F1, written as $\sim$; *see* **Multivalued Logics**). Thus, if the lexical meaning of *all* is made to incorporate the condition that $[[F]] \neq \emptyset$ as a precondition for informative use in a consistent context, ABPC is allowed to apply again in full force, but only within the confines of a situation in which $[[F]] \neq \emptyset$. In situations that do not satisfy that condition, the use of *all* will result in radical falsity. Although no such provision is required for the lexical meaning description of *some*, as previously mentioned, **I** and **I*** sentences are still radically false when $[[F]] = \emptyset$ because the *Principle of Extensionality* amounts to the presuppositional requirement of actual existence for the reference values of the terms of the *G*-predicate. This *presuppositional predicate calculus* (PPC) is represented in Figure 5, where the bold circle delineates the area of applicability of traditional bivalent ABPC. Space 4 is useful not only as a logical safety net but also in speech to mark a sentence as being unfit for the current discourse. This is done with the help of the radical negation NOT, emphatically accented, which makes itself useful in language as a metalinguistic discourse corrector, as in *all mermaids do* NOT *swim; there* ARE *no mermaids!*

It thus seems that SMPC should be rejected as a candidate for the status of 'logic of language.' This in itself is a momentous conclusion given the almost universal, yet false, belief that no other consistent predicate logic is possible. There is, however, a redeeming feature. Had it not been for SMPC, the

Figure 5 The VS model for PPC.

logical language of predicate calculus ($L_{PC\text{-}Peano}$) in which it is formulated would not have existed. After a first unsuccessful attempt at a logical language in Frege (1878), PL_{PC} was created by Giuseppe Peano around 1900 and adopted by Alfred Whitehead and Bertrand Russell in their *Principia Mathematica* of 1910–1913. Since then, $L_{PC\text{-}Peano}$ has become the stock in trade of all logic.

The main innovation of $L_{PC\text{-}Peano}$ consisted in the introduction of separate symbols for *all* (∀) and *some* (∃) as variable binders in propositional functions. A propositional function is a propositional sentence in $L_{PC\text{-}Peano}$ with at least one term missing – that is, filled by a variable. Thus, if Bald(Jack) is a propositional sentence with a truth value, Bald(x) is a propositional function that will be true or false when a value is filled in for the variable x. Quantifiers such as ∀ and ∃ are a further way of turning a propositional function into a propositional sentence. The universal quantifier ∀ turns a propositional function into a sentence with a truth value, in that it requires for truth that any arbitrary value for x (within the defined range of x) will yield truth. The existential quantifier ∃ produces truth when at least one value for x yields truth. A sentence such as *All humans are mortal* is rendered in $L_{PC\text{-}Peano}$ as (1a), and *Some humans are mortal* is rendered as (1b). The symbol → stands for the material implication 'if . . . then', and ∧ stands for the conjunction 'and'. Both full propositional sentences and propositional functions can be negated and placed under any binary propositional operator.

(1a) $\forall x(\text{Human}(x) \rightarrow \text{Mortal}(x))$
('for all x, if x is human, x is mortal')

(1b) $\exists x(\text{Human}(x) \wedge \text{Mortal}(x))$
('there is an x such that x is human and x is mortal')

Example (1a) is true when any arbitrary value for x makes it true. If the value of x is not human but, say, a tree, then the whole implication is automatically true. If for all *human* values of x it turns out that they are also mortal, then (1a) is true. Falsity for (1a) can thus be brought about only by one or more values for the variable x that are human but not mortal – so-called counterexamples. For the truth of (1b), it is required that there be at least one x such that x is both human and mortal.

$L_{PC\text{-}Peano}$ makes it possible to treat sentences with more than one argument term and to quantify each such term. Thus, a sentence such as *Every boy gave some present to some girl* can be rendered as (2) (disregarding tense):

(2) $\forall x(\text{Boy}(x) \rightarrow \exists y(\text{Present}(y) \wedge \exists z(\text{Girl}(z) \wedge \text{Give}(x, y, z))))$
('for all x, if x is a boy then there is a y such that y is a present and such that there is a z such that z is a girl and x gives y to z')

For the analysis of quantification in natural language sentences, however, this 'translation' method is now widely considered inadequate, mainly because it cannot be used for quantifiers such as *most* or *half*. For this reason, Barwise and Cooper (1981) decided to adopt the notion of *generalized quantifier*, introduced in Mostovski (1957). The actual logic, in the sense of a system of entailment schemata, is not affected by this innovation, which is merely syntactic. In the syntax of this modified logical language $L_{PC\text{-}Mostovski}$, a quantifier is a binary higher order predicate – that is, a binary predicate over sets, not over individuals. Instead of writing (1a) and (1b), we now write (3a) and (3b), respectively; (2) is now rendered as (3c):

(3a) $\forall x(\text{Human}(x), \text{Mortal}(x))$
('the set of humans is included in the set of mortals')

(3b) $\exists x(\text{Human}(x), \text{Mortal}(x))$
('there is a nonnull intersection of the set of humans and the set of mortals')

(3c) $\forall x(\text{Boy}(x), \exists y(\text{Present}(y), \exists z(\text{Girl}(z), \text{Give}(x, y, \text{to } z))))$
('the set of boys is included in the set of those individuals a such that for each a there is a nonnull intersection of the set of presents and the set of objects b such that there is a nonnull intersection of the set of girls and the set of persons that a gives b to')

$L_{PC\text{-}Mostovski}$ fits both the syntactic and the semantic facts of language remarkably well and is now widely

used in philosophical, semantic, and logical studies of language. It is important to realize that the syntax of a logical language is to a large extent independent of the precise semantics of the quantifiers and the negation: The language may stay the same while the semantic description of the operators involved varies, and vice versa. The main question regarding the logic of language is now no longer the syntax of the logico-semantic 'translations' of sentences because $L_{PC\text{-}Mostovski}$ has so far proved adequate. The main problem still outstanding is, rather, the precise semantic description of whatever logical constants are detected, in particular the words *not*, *all*, *some*, *and*, *or*, and *if*. (*May* (*can*) and *must* are likewise plausible candidates for the status of logical constants in a modal logic, and other candidates may yet be discovered.) So far, the syntax of $L_{PC\text{-}Mostovski}$ has proved highly successful not only as regards the expression of the logical properties of propositions, but also for the purpose of relating its expressions to surface sentences in natural languages. It has vastly extended the scope of the logical analysis of natural language sentences and is probably the greatest contribution made by modern logic to the logico-semantic analysis of natural language.

Propositional Calculus

In propositional calculus, the most current logical constants are *not*, *and*, *or*, and *if* ... *then*. The variables, say *P*, *Q*, *R*, ..., range over propositional sentences. Propositional calculus was developed in the Greek world by Stoic philosophers during the 3rd and 2nd centuries B.C.E. (Łukasiewicz, 1934). *Not* is standardly symbolized as ¬ and is the bivalent truth-value toggle described here. *And* is standardly written as ∧, *or* as ∨, and *if* ... *then* as →. The semantics of these constants (operators) is usually given in terms of the truth tables shown in Figure 6.

Strictly speaking, the material implication operator → is superfluous because $P \rightarrow Q \equiv \neg P \vee Q$. Yet it is usually specified as a separate operator rendering natural language *if* ... *then*. That it does not do so has been known for two millennia, yet it continues to figure in logic textbooks as a translation of *if* ... *then*.

Of greater logical importance is the fact that the logic of *and* and *or* is isomorphic with the logic of *all* and *some* in ABPC. When $P \wedge Q$ stands for **A**, $P \vee Q$ for **I**, $\neg P \vee \neg Q$ for **A***, and $\neg P \vee \neg Q$ for **I***, there is full isomorphism. The following notation is used:

AND: $P \wedge Q$	**OR**: $P \vee Q$
¬AND: $\neg(P \wedge Q)$	**¬OR**: $\neg(P \vee Q)$
AND*: $\neg P \wedge \neg Q$	**OR***: $\neg P \vee \neg Q$
¬AND*: $\neg(\neg P \wedge \neg Q)$	**¬OR***: $\neg(\neg P \vee \neg Q)$

Propositional calculus can now be represented as the Square of Oppositions of Figure 7A. The VS model for propositional calculus is as in Figure 7B, which is isomorphic with Figure 3A. The 'conversions' in predicate calculus correspond to the *De Morgan's laws* in propositional calculus; they convert ∧ into ∨ and vice versa, provided both an external and an internal negation are added (or removed): $\neg(P \wedge Q) \equiv \neg P \vee \neg Q$, and $\neg(P \vee Q) \equiv \neg P \wedge \neg Q$.

It has often been observed that the universal quantifier is somehow related to *and* and the existential quantifier to *or*. This relation is usually spelled out by saying that *all F is G* is equivalent to '$G(f_1) \wedge G(f_2) \wedge G(f_3) \wedge \ldots$', and that *some F is G* is equivalent with

'$G(f_1) \vee G(f_2) \vee G(f_3) \vee \ldots$', until all members f_n of $[[F]]$ have been enumerated. Yet this is only so if $[[F]] \neq \emptyset$. If $[[F]] = \emptyset$ there will be neither a conjunction nor a disjunction of its members. In general, since ABPC was rejected in favor of SMPC, which had its logic reduced to the conversions, the obvious parallelism of $\forall$ with $\wedge$ and of $\exists$ with $\vee$ has been more of an embarrassment than of a help to logicians. Yet, if ABPC can be restored to its traditional position, the isomorphism of ABPC with propositional calculus will be a reason for looking further into logical systems with such properties as ABPC and propositional calculus have in common.

Unlike ABPC, propositional calculus is not logically faulty. It does not need a fourth space because there is no null class to cater for. Yet it can be made trivalent so as to cater for presuppositions (Seuren *et al.*, 2001). The minimal, presupposition-preserving negation ($\sim$) toggles between T and F1 and yields F2 in cases of presupposition failure. The radical presupposition-canceling negation ($\sim$) yields T only in cases of presupposition failure and yields F1 otherwise. (The standard negation $\neg$ is equivalent with the disjunction of minimal and radical negation: $\sim P \vee \simeq P \equiv \neg P$.) Conjunction ($\wedge$) selects F2 over F1 and T, and F1 over T; disjunction ($\vee$) selects T over F1 and F2, and F1 over F2, as shown in Figure 8.

When the logic of language is seen as being defined by the semantic descriptions of the logical constants involved, an entirely new perspective on logic emerges, one that has so far hardly been explored.

Propositional Attitude Ascription: Philosophical Aspects

L Clapp, Illinois Wesleyan University, Bloomington, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Paradigmatic **propositional attitude ascriptions** (in English) are sentences of the form **A V**s **that S,** where **A** is a singular definite noun phrase referring to a rational agent, **S** is a sentence, and **V** is a propositional attitude verb. Paradigmatic propositional attitude verbs include 'believe', 'doubt,' 'realize,' 'hope,' 'regret,' etc. Such verbs refer to **intentional mental states** with **representational content**, where this content can be evaluated for truth or falsity, and thus can be identified with a **proposition**. (What are sometimes called *verbs of saying*, e.g., 'say,' 'deny,' 'announce,' are closely related to, but typically distinguished from, propositional attitude verbs.) Because propositional attitude verbs refer to intentional states with propositional content, it is natural to endorse a **relational analysis** of propositional attitude ascriptions: an assertion of 'John hopes that Mary won' says that the referent of 'John' bears the mental relation (or *attitude* in Russell's 1940 terminology) referred to by 'hopes' toward the proposition expressed by the complement clause 'that Mary won.' Similarly, an assertion of

Propositional Attitude Ascription: Philosophical Aspects

L Clapp, Illinois Wesleyan University, Bloomington, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Paradigmatic **propositional attitude ascriptions** (in English) are sentences of the form **A V**s **that S,** where **A** is a singular definite noun phrase referring to a rational agent, **S** is a sentence, and **V** is a propositional attitude verb. Paradigmatic propositional attitude verbs include 'believe', 'doubt,' 'realize,' 'hope,' 'regret,' etc. Such verbs refer to **intentional mental states** with **representational content**, where this content can be evaluated for truth or falsity, and thus can be identified with a **proposition**. (What are sometimes called *verbs of saying*, e.g., 'say,' 'deny,' 'announce,' are closely related to, but typically distinguished from, propositional attitude verbs.) Because propositional attitude verbs refer to intentional states with propositional content, it is natural to endorse a **relational analysis** of propositional attitude ascriptions: an assertion of 'John hopes that Mary won' says that the referent of 'John' bears the mental relation (or *attitude* in Russell's 1940 terminology) referred to by 'hopes' toward the proposition expressed by the complement clause 'that Mary won.' Similarly, an assertion of

'John doubts that Tom is happy' says that John bears a different relation, viz. doubting, toward a different proposition, viz. that Tom is happy.

Analytic philosophers have been, and continue to be, concerned to formulate an adequate semantic analysis of propositional attitude ascriptions for several reasons. One reason stems from philosophers' desire to understand the nature of mental states. What is, e.g., a belief? Is the existence of beliefs compatible with **physicalism**? If not, then should we be **eliminativists** about mental states, and deny that they really exist, or should we reject physicalism in favor of some sort of **dualism**? How can a mental state **represent** things as being a certain way? i.e., what is it for one entity to be **about** another? Does having a belief require one to instantiate some sort of internal representational state (as **cognitivists** claim), or is it merely a matter of being disposed to behave in various ways (as **behaviorists** claim)? Whatever view one adopts toward these broader philosophical issues concerning the nature of mental states must be compatible with an adequate semantic analysis of how we talk about such states.

Another reason, perhaps the principle reason, philosophers are concerned with propositional attitude ascriptions stems from the close relationship between natural language and thought, and the apparent **compositionality** exhibited by both. What we can think is what is expressed by utterances of declarative sentences; if what we think are **thoughts**, and if what is expressed by utterances of declarative sentences are propositions, then what we think are propositions. Moreover, philosophers have argued that in order to explain the **productivity, interpretability,** and **systematicity** of language, and thus thought, some sort of **principle of semantic compositionality** must hold for language, and thus thought (see Frege (1914) and Davidson (1965) for appeals to productivity and interpretability. See Evans (1982) and Fodor (1998) for appeals to systematicity. Frege also appealed to compositionality to explain the **unity of the proposition**. See Frege (1891 and 1892b). Consequently, many analytic philosophers have endorsed some version of the following **principle of semantic compositionality**:

> The proposition expressed by a sentence S in a context c is a function of (i) the **logical form** of S, and (ii) the **semantic values** invoked by S in c.

(The relativization to context is necessary to account for sentences containing **context sensitive** words.) The reason that philosophers interested in language and thought have been especially concerned with propositional attitude ascriptions is that these sentences provide apparent counterexamples against this otherwise well-motivated principle; this is known as the **opacity** problem for attitude ascriptions. The focus of my remarks here will be on the opacity problem and influential proposals for its solution.

Consider the classic case of the hapless ancient astronomer: He used 'Hesperus' to refer to the first heavenly body to appear at dusk, and 'Phosphorus' to refer to the last heavenly body to disappear at dawn. But he did not realize that these names are coreferential; they both refer to Venus. Now consider the following attitude ascriptions:

(1) The astronomer believed that Hesperus was visible at dusk.

(2) The astronomer believed that Phosphorus was visible at dusk.

Given the astronomer's ignorance of the identity of Hesperus and Phosphorus, (1) is true and (2) is false. But that (1) and (2) differ in truth value is at least an apparent counterexample to the compositionality principle: If it is granted that (1) and (2) have the same logical form, and that the semantic value contributed by a word is its referent, then, given that 'Hesperus' and 'Phosphorus' are coreferential, semantic compositionality seems to require that (1) and (2) express the same proposition, and thus cannot differ in truth value. The opacity problem is sometimes called *substitution failure*: in (1) 'Phosphorus' cannot be substituted ***salva veritate*** for 'Hesperus.' Linguistic environments in which coreferential terms cannot be substituted ***salva veritate*** are known as **opaque**, as opposed to **transparent**, contexts.

Responses to the opacity problem can be divided into **conservative** proposals and **radical** proposals. Conservative proposals attempt to preserve the principle of semantic compositionality by somehow explaining away the apparent counterexamples. Conservative proposals can be subdivided into **semantic** conservative proposals, which appeal to the **meanings** of expressions to explain away the apparent counterexamples, and **pragmatic** conservative proposals, which appeal to how expressions are **used.** In contrast to conservative proposals, **radical proposals** accept the apparent counterexamples provided by attitude ascriptions, and thus reject the principle of semantic compositionality and offer alternative conceptions of semantics in its place.

To propose a **semantic conservative solution** to the opacity problem, then, is to provide an account of semantic values, and how they are invoked and combined, which preserves the above principle of compositionality yet explains why, e.g., (1) and (2) express different propositions. If the datum that (1) and (2) express different propositions is granted, and it is granted that (1) and (2) have the same logical form, then the general strategy one must adopt is clear: one

must argue that (1) and (2) somehow invoke additional, extrareferential, semantic values. Semantic conservative proposals all have this general strategy in common; where they differ is over **what** they take the requisite additional semantic values to be, and over **how** attitude ascriptions invoke different such additional semantic values.

The first, and probably most influential, semantic conservative proposal was presented by Frege (1892a). Indeed, Frege was the first to clearly formulate the opacity problem, and most subsequent work on the problem is a development of, or response to, Frege's seminal paper. A key feature of Frege's proposal is the thesis that words embedded in the complement clauses of attitude ascriptions **shift referents**; when words occur embedded in such **opaque** contexts, their semantic values are not their 'ordinary referents,' but are instead more finely individuated entities, which Frege called 'indirect referents.' Frege posited abstract objects he called **senses** to serve as indirect referents. A sense of a word is alleged to be a 'mode of presentation' of the referent of the word (if the word has a referent). To return to the hapless astronomer, Frege would say that the referent, Venus, is presented to the astronomer in two different ways; one of these ways is the sense of 'Hesperus,' and the other is the sense of 'Phosphorus.' The astronomer fails to recognize that Hesperus is Phosphorus because he fails to realize that these different modes of presentation are in fact modes of presentation of, or ways of thinking about, the same referent. If it is granted that 'Hesperus' and 'Phosphorus,' though coreferential, nonetheless express different senses, then, because of referent shifting, (1) and (2) invoke different semantic values. And consequently, that these sentences express different propositions, and have different truth values, is no threat to semantic compositionality.

Many theorists endorse Frege's thesis that words embedded in the complement clauses of attitude ascriptions shift referents, yet, influenced by broader philosophical commitments, they reject senses, the abstract objects Frege posited to serve as indirect referents. Other sorts of entities posited to serve as indirect referents include **intensions** (Montague, 1974), sentences (Carnap, 1946), and **mental representations** (Fodor, 1978). All theories which allow for referent shifting, however, face a common difficulty: As Quine (1956) noted, attitude ascriptions are ambiguous (or at least context sensitive). For some utterances of attitude ascriptions, what is relevant for determining truth conditions is simply the referent of an embedded word, rather than the word, or some other sort of indirect referent. And for these so-called ***de re*** utterances of attitude ascriptions, Frege's referent shifting thesis is inappropriate. But, as Frege noted, for other, so-called ***de dicto***, utterances of attitude ascriptions, it seems that something other than the referents of embedded words is relevant for determining truth conditions. It is now widely accepted that in different contexts the same attitude ascription (sentence type) can express different truth conditions; in particular, some utterances of, e.g., the type of (1) are ***de re*** (or **transparent**), while other utterances like (1) are ***de dicto*** (or **opaque**).

The recognition of the context sensitivity of attitude ascriptions has led philosophers to add complexities to the semantic conservative strategy. Quine (1956) proposes that, if propositional attitudes are to be countenanced at all, propositional attitude verbs ought to be treated as ambiguous between a **relational** (***de re***) sense, and a **notional** (***de dicto***) sense. More recent proposals build on Carnap's (1946) theory, and identify indirect referents not with words, but with abstract structures composed of both words and their ordinary referents (relative to a context) combined. These Carnap-inspired theories attempt to account for the context sensitivity of attitude ascriptions by allowing what is necessary for an agent to hold the relevant mental relation to the combined entity to vary across contexts (see Richard, 1990 and Higginbotham, 1991).

Thus far, I have reviewed semantic conservative proposals that follow Frege in maintaining that words in complement clauses of attitude ascriptions shift their referents; where the proposals discussed thus far have differed from each other concerns **what** the additional semantic values are. Other semantic conservative proposals, however, disagree with Frege not only concerning **what** the requisite additional semantic values are, but they also reject Frege's referent shifting thesis. An early alternative to Frege's indirect reference strategy was proposed by Russell (1919). Russell's proposal preserves the simple idea that semantic values are **always only** ordinary referents, but he achieves this result at the cost of allowing the **logical form** of a sentence to differ significantly from its **surface form**. According to Russell, what appear to be referring terms, e.g., 'Hesperus' and 'Phosphorus,' are merely abbreviations for "denoting phrases" composed of quantifiers and unpronounced genuine referring terms; Russell called these posited unpronounced genuine referring terms "logically proper names." According to Russell then, despite appearances, Venus is not the referent of any genuine referring term in the logical form of either (1) or (2). Rather, the apparent names 'Hesperus' and 'Phosphorus' abbreviate denoting phrases comprised of different, noncoreferential, logically proper names. Thus, that (1) and (2) express different propositions is

not a counterexample to semantic compositionality, because, according to Russell, the sentences invoke different semantic values. (Not surprisingly, Russell never presents a full reduction of an apparent name into a denoting phrase comprised of logically proper names.)

A more recent proposal similar in spirit to Russell's is the "hidden indexical" analysis (see Schiffer, 1977 and Crimmins, 1992). This proposal maintains that the additional semantic values required for distinguishing the propositions expressed by utterances of (1) and (2) are the referents of 'hidden' – phonologically unrealized – indexical items that are somehow present in the logical form, but not in the surface form, of the sentence. Crimmins takes the posited hidden indexicals to refer (in contexts) to "mental particulars," token mental representations that, similar to Frege's senses, are ways of thinking of ordinary referents. The hidden indexical analysis thus does not deny that, e.g., Venus is a semantic value invoked by both utterances (1) and (2), because Venus is the referent of both 'Hesperus' and 'Phosphorus.' But that such utterances express different propositions is nonetheless not a counterexample to semantic compositionality because the presence of hidden indexicals allows the utterances to invoke different mental particulars as 'unarticulated' semantic values.

Another influential semantic conservative proposal that rejects referent shifting is Davidson's (1968) "paratactic" analysis of indirect speech. Davidson proposes that an indirect speech report with the surface form 'A said that S' has the logical form of **two** sentences: first, 'A said **that**,' and second, 'S.' The word 'that' in the first sentence is interpreted as a **demonstrative**, and in an utterance with the surface form 'A said that S,' the demonstrative refers to the subsequent **utterance** of 'S.' Thus, in Davidson's proposal, the additional semantic value invoked by an utterance of an indirect speech report is the very act of uttering the sentence embedded in the complement clause. According to Davidson's proposal, an utterance with the surface form 'A said that S' is true just in the case the agent referred to by 'A' performed an utterance that is relevantly similar to the referent of 'that,' where this referent is the **utterance** of the embedded 'S.' Davidson applied his analysis only to indirect speech reports, but others, such as Lepore and Loewer (1989), have extended Davidson's analysis so that it applies to attitude ascriptions.

Whereas semantic conservative proposals accept that, e.g., (1) and (2) express different propositions and attempt to reconcile this datum with the principle of semantic compositionality, **pragmatic conservative proposals** reject the datum and thereby undermine the apparent counterexample to semantic compositionality. According to pragmatic conservative proposals, (1) and (2) do not present a counterexample to compositionality because, despite our pretheoretic judgments to the contrary, they do not express different propositions, and they do not differ in truth value. Support for this seemingly implausible strategy comes from two principle sources: First, there are influential arguments due to Kripke (1972) and Kaplan (1977) in support of the **thesis of direct reference**, according to which the only semantically relevant feature ever associated with some terms – names, demonstratives, and indexicals being the paradigmatic cases – is the referent of the term. The thesis of direct reference thus entails that, e.g., utterances (1) and (2) express the same proposition. Second, there is Grice's (1975) distinction between **what is said** by an utterance and **what is merely implied** by an utterance. According to Grice, **what is said** is the domain of **semantics** and thus must conform to the compositionality principle, while **what is implied** is the domain of **pragmatics**, and thus need not conform to the principle. According to the pragmatic conservative strategy then, utterances (1) and (2) semantically say the same thing, but they pragmatically imply different things. And our pre-theoretic judgment that utterances (1) and (2) say different things is a result of our naively conflating **semantically expressed** information with **pragmatically implied** information. Pragmatic conservative proposals are developed by Salmon (1986) and Soames (2002).

In contrast to **conservative proposals** which attempt to preserve semantic compositionality by somehow explaining away the at least apparent counterexamples posed by attitude ascriptions, **radical proposals** accept the counterexamples and reject semantic compositionality. Given the fundamental role that the principle of compositionality has played in semantics and analytic philosophy generally, a theorist who endorses a radical proposal must provide an alternative conception of what it is to provide a semantic analysis. Moreover, this alternative conception must be at least compatible with the phenomena of **productivity**, **interpretability**, and **systematicity**. One sort of radical proposal falls within the broader movement known as **Radical Pragmatics**. Radical Pragmatics is characterized by the thesis that the linguistic meaning associated with an utterance underdetermines what is said by the utterance; i.e., knowing the logical form of an utterance and knowing the referents of all the words (or other relevant features) does not suffice for determining what is said by the utterance; in order to arrive at something truth-evaluable, additional processing is required. **Relevance Theory,** as proposed by Sperber and Wilson (1986), is a

paradigmatic example of Radical Pragmatics. Thus, from the perspective of Radical Pragmatics, it is not particularly problematic that utterances (1) and (2) express distinct truth conditions. A version of Radical Pragmatics is applied to attitude ascriptions in Bach (1997).

Another sort of radical proposal falls within the broader movement known as **Dynamic Semantics**. According to Dynamic Semantics, the semantic content of a declarative utterance is not a truth–evaluable proposition, but rather linguistically encoded general instructions (i.e., a 'context change potential') for updating the set of beliefs shared between the speaker and his audience (i.e., the 'common ground'). To determine **what is said** by an utterance, one must apply the linguistically encoded general instructions to the set of shared beliefs. Thus, **what is said** depends not only upon the logical form of the uttered sentence and the semantic values of the words in it, but also upon what the shared beliefs of the speaker and his audience happen to be. A paradigmatic example of Dynamic Semantics is **Discourse Representation Theory,** as proposed by Kamp and Ryle (1993). Because utterances (1) and (2) encode different instructions for updating sets of shared beliefs, **what is said** by such utterances (relative to the same set of shared beliefs) can differ. Thus, from the perspective of Dynamic Semantics also, it is not particularly problematic that such utterances are interpreted as expressing distinct truth conditions. This sort of dynamic approach is applied to the phenomenon of opacity in Asher (1993).

Propositional Attitudes

K Jaszczolt, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

Talking about people's states of mind is difficult for various reasons. The most interesting from the linguistic point of view is the problem of the identity of meaning between the clause uttered by a reporter about someone's state of mind and the sentence that the holder of this state would use to express it. Such reports are normally composed of a *that*-clause expressing a proposition toward which the attitude is held and an assignment of an attitude such as belief, doubt, or fear to a person, as in (1).

(1) Tom believes that Peter Carey is a great novelist.

Conceiving this standard form to express a relation between a person and a proposition, Bertrand Russell called such states propositional attitudes, and the term has remained in common philosophical and linguistic parlance ever since, in spite of the fact that the problem of the object of propositional attitudes (variously regarded as a proposition, sentence, thought, constituents of a proposition, etc.) is still widely disputed in the literature.

Reporting on people's beliefs gives rise both to theoretical and practical problems. In other words, it is interesting not only from the semantic and pragmatic point of view but also from the perspective of an average language user who wishes to make an accurate statement. For example, if the believer utters (2), the reporter may have doubts whether the believer understands the statement or merely repeats a half-understood astronomical statement. Alternatively, the reporter may not be in a position to report on the belief faithfully and with understanding, due to not knowing what the statement is about.

(2) Red giants become white dwarfs.

These discrepancies between the knowledge base of the believer and that of the reporter, as well as the practical difficulty with assessing how much the believer actually knows about the referent, lead to common problems with belief ascription.

Another problematic case is when the believer is referentially mistaken and uses a name or description that does not refer to the intended individual. In (3), the believer may have, for example, Pablo Picasso, a Spanish painter, in mind:

(3) The best Italian painter painted this picture.

Moreover, belief can also be ascribed on the basis of nonlinguistic evidence. Sentence (4) can be uttered of someone carrying an umbrella on a sunny day:

(4) He believes it is going to rain.

In practice, the reporter assumes that the believer has a clear idea what or who he or she is talking about. However, if there are reasons for doubt, the reporter has to assess all the relevant contextual information before making a report in order to make the report valid.

In the philosophy of language, it has been widely assumed that propositional attitude reports are ambiguous between the transparent reading and the opaque reading. Sentence (5a) has two semantic interpretations, (5b) and (5c), that correspond to the wide and narrow scope of the existential quantifier, respectively.

(5a) Tom believes that the king of France is bald
(5b) $\exists x\ (KoF(x)\ \&\ \forall y\ (KoF(y) \supset y = x)\ \&\ Bel_T\ Bald\ (x))$
(5c) $Bel_T\ \exists x\ (KoF(x)\ \&\ \forall y\ (KoF(y) \supset y = x)\ \&\ Bald\ (x))$

In these examples, Bel_T stands for 'Tom believes that' and *KoF* stands for 'king of France' (see also Russell, 1905, 1919; Quine, 1956; Neale, 1990). When the reporter means (5b) by (5a), he or she ascribes to Tom a belief about a particular, known individual (*de re*). When he or she means (5c) by (5a), the reporter says that Tom believes in the existence of the king of France and ascribes to him a certain property (*de dicto*). The reading in (5b) is transparent and in (5c) opaque, for the reasons to become clear in what follows. However, these logical forms cannot express the complexities of belief ascription. When Tom is referentially mistaken and the reporter is aware of it, he or she may substitute a correct description or name, as in (5d), where *KoS* stands for 'king of Sweden'.

(5d) $\exists x\ (KoS(x)\ \&\ \forall y\ (KoS(y) \supset y = x)\ \&\ Bel_T\ Bald\ (x))$

So, there does not seem to be a strict ambiguity here from the perspective of utterance interpretation. Nor do the logical forms here capture the extent of the problem with the varieties of *de re* and *de dicto* beliefs and *de re* and *de dicto* (roughly corresponding to transparent and opaque) reports. The interpretations of (5a) have to resort to pragmatics. But before venturing into pragmatic processing, let us focus on the logical form that is the starting point for the application of such processes.

The *de re*/*de dicto* distinction has to be kept apart from the distinction between factive and nonfactive attitudes and factive and nonfactive attitude verbs. Factives are verbs that give rise to a proposition whose truth entails that the proposition expressed by the *that*-clause is itself true. For example, *A knows that p* entails that *p* is true. Nonfactives,

such as *believe* or *think*, do not require that the embedded proposition be true. Moreover, verbs such as *wish* or *imagine* are sometimes said to belong to a third category, called counterfactives (or contrafactives), in that they can be construed as entailing the falsity of the embedded proposition. Nonfactives, in particular the verb *believe*, have been the most widely studied of all. This is because *de dicto* nonfactive reports do not, by definition, carry the truth entailment of the embedded proposition and hence express various degrees of detachment from the proposition.

That-clauses in belief reports pose semantic problems because their content has to be evaluated in an intensional (nonextensional) propositional attitude context. In such contexts, substituting a coreferential term in the embedded clause may lead to a change of the truth value. This problem has traditionally been discussed in the literature as the nonapplicability of Leibniz's Law. Leibniz's Law states that two things are identical with one another if they are mutually substitutable, preserving the truth of the sentence. In Leibniz's formulation, quoted after Frege, "*Eadem sunt, quae sibi mutuo substitui possunt, salva veritate*" (Frege, 1892/1997: 570). This law also has a more general claim, dubbed in the literature the identity of indiscernibles: If things have all properties in common, then they are identical and they are one thing. Now, when we apply this law to belief reports, we talk about the substitutivity of terms or expressions rather than 'things.' To rephrase the law: If all that can be said of one thing can be said of another, then it is said about one thing in two guises. In addition, Leibniz's Law has been applied to attitude contexts in a more recent version that is in fact due to Quine and that states that, if things are identical (i.e., they are one), then they have all properties in common. This law is dubbed the indiscernibility of identicals. In other words, if we take one object described in two different ways, whatever can be said about it under one guise can also be said about it under the other guise. In other words, again, if A and B are identical, then anything that is true of A is also true of B:

$$\forall x \forall y (x = y \supset (F(x) \supset F(y)))$$

In talking about attitudes, we follow here the common practice and adopt this version of the law, allowing for its extension to the indiscernibility of identicals and remembering that this was not Leibniz's original intent.

Belief reports are thus nonextensional (intensional) contexts in which Leibniz's Law does not hold. However, they are also sometimes called hyperintensional, in that expressions that can be substituted for one another in other intensional (e.g., modal) contexts cannot always be substituted in attitude contexts. Such expressions have the same intension and, yet, are not substitutable. For example, coreferential proper names are substitutable in modal contexts but not in attitude context. Alternatively, instead of the category of hyperintensionality, we can distinguish degrees to which the guise under which a belief is held contributes to the semantics, as it is developed next.

Now, coming back to (5b) and (5c), we can see that Leibniz's Law of substitutivity *salva veritate* does not work on the opaque (5c) reading. In (5b), on the contrary, the discourse is about a particular known individual and this reading is transparent to substitutions of coreferential terms. In order to preserve compositional semantics, it has been suggested, among others, that we have to establish under which mode of presentation (sense or guise) the object referred to is known to the believer. For instance, (6) and (7) may or may not express the same proposition (i.e., may or may not have the same informational content), depending on the modes of presentation that belong to the believer's knowledge base:

(6) Bernard J. Ortcutt is an honest citizen.

(7) The man in the brown hat is an honest citizen.

The speaker of (6) may not consent to believing (7) because her or she may not know that the description in (7) refers to the same individual. So, the core point in discussing attitude reports is to agree on what reference is in such nonextensional contexts and how to use this notion of reference in the semantics. The failure of substitutivity of coreferential expressions suggests that we have to either abandon compositional semantics or incorporate contextual information into semantic theory.

Various solutions have been suggested. According to Frege (1892), the role of reference in intensional contexts is taken by sense, that is, by an objective equivalent of a mode of presentation. Next, the *that*-clause can be taken to refer to a sentence rather than a proposition (see e.g., Bach, 1997). Quine (1956) postulated degrees of intensions for quantifying into such contexts. More recently, there have been various suggestions to incorporate the mode of presentation into the logical form, stemming from the hidden-indexical theory (Schiffer, 1992, 1996), developed also in Crimmins and Perry's (1989) and Crimmins's (1992) 'notion', which is an unarticulated constituent of the proposition. These are sometimes understood as a covert *so* as in *A so-believes that* . . . or *so-labeled* as in *A believes that B, so-labeled, Φs* (Forbes, 1990, 1997). Jaszczolt (1999, 2000) proposed degrees of

semantic significance of the mode of presentation, depending on the default or nondefault status of the interpretation of the attitude report. The literature also offers ample constructive criticism of the Fregean direction (Salmon, 1986; Soames, 1987; Donnellan, 1989; Recanati, 1993; Clapp, 1995, 2000). At the other end of the spectrum, neo-Russellian approaches (e.g., Salmon, 1986; Soames, 1987, 1995) denied the contribution of the mode of presentation to the semantics of attitude reports. Instead, the semantic content of a sentence is a singular proposition. Richard (1990, 1995) suggested that the verb *believe* is indexical, thereby making the verb contextually sensitive. Larson and Ludlow (1993) proposed composites of linguistic forms and extra-linguistic objects, called by them interpreted logical forms. In this way, they captured the relevance of the actual expression that is used to refer in the sentence. Stanley (2000) suggested that all the contextual factors that affect truth conditions can be traced to the elements in the syntactic structure and that, therefore, there are no unarticulated constituents. Finally, if we extend the category of attitude verbs to include *say* followed by a *that*-clause, there is Davidson's (1968–1969) paratactic account in which a demonstrative *that* refers to an utterance. Davidson advocated a semantic innocence view, according to which an expression in an attitude report contributes exactly what it does in nonintensional contexts.

Now, neo-Russellians respected semantic innocence but denied the semantic significance of modes of presentation. Intuitively, what they said is that, although substitutivity in attitude reports does not **seem** to hold, **in fact** it does: Substitution does not affect the truth value. On the other hand, hidden-indexical theorists could only preserve semantic innocence when they gave up compositionality. Hidden indices, standing for modes of presentation, have no counterpart in grammar, and hence the meaning becomes noncompositional. Be that as it may, some form of mode of presentation is indispensable in talking about propositional attitudes and attitude reports. Even if we attempt to do without it in semantic representation, it appears in pragmatics. Or, more commonsensically plausible, it comes from pragmatics but intrudes in the semantic representation of attitude reports. How much this mode of presentation contributes to the proposition expressed is the focus of ongoing discussion. In Schiffer's hidden-indexical theory mentioned, belief is a three-place relation among the believer, the proposition whose structure can be taken into account, and a mode of presentation under which the person believes this proposition. In (9), Φ^*m is a type of mode of presentation determined by the context, and <> indicate the intensions (see Schiffer, 1992: 503).

(8) Ralph believes that Fido is a dog.

(9) $(\exists m)\,(\Phi^* m \;\&\; \mathrm{Bel}\,(\mathrm{Ralph}, \langle \mathrm{Fido}, \mathrm{doghood}\rangle, m))$

This opens up new problems: (1) What information falls under Φ^*m, (2) where does it come from, and (3) why is Φ^*m conceived of as a constituent of the logical form of sentences? Here two general answers are available: Contextual information included in the mode of presentation can contribute to the propositional form of an utterance (contextualism), or contextual information functions separately from the proposition, as implicatures (anti-contextualism; Recanati, 1994). Although it is commonly accepted that this contextual information is needed in reporting on beliefs, the theoretical question remains as to whether it contributes to the truth conditional representation. Such modes of presentation may be too detailed, too fine-grained, yet **some** contextual information that pertains to the identification of the belief may be semantically relevant (see Jaszczolt, 2000). To conclude, two important issues still remain in the focus of discussion: (1) Does pragmatic information figure in specifying what the speaker believes, and if so, to what extent; and (2) where does the boundary lie between the semantic representation and the pragmatic information? Both questions are directly related to the issue of the semantics/pragmatics interface and the existence of salient default interpretations.

Now, it has to be pointed out that the ambiguity of reading of attitude reports is engendered even by proper names and even where substitutivity is not the case. In the puzzle presented by Kripke (1979), the problem of reporting on beliefs involves the principle of translation (if a sentence in one language is true, its translation into another language is also true) and the principle of disquotation (if a speaker assents to 'p', then he believes that 'p'). Pierre, a speaker of French who lives in France, holds a belief about a certain city unknown to him, called Londres, that it is pretty. His belief, uttered in (10), can be reported on as in (11).

(10) Londres est jolie.

(11) Pierre believes that London is pretty.

Next, Pierre moves to London and acquires a belief expressed by him in (12), while still holding (10).

(12) London is not pretty.

Kripke does not offer a solution. But it seems that in order to avoid contradiction, we have to accept that proper names have some semantically

significant mode of presentation that comes with the belief. Or we have to anchor the proper names to real or imagined objects, as was done in Discourse Representation Theory (Asher, 1986; Kamp, 1990). All in all, the content and the semantic status of the mode of presentation seem to be the key to the puzzles surrounding attitude ascription.

When an English speaker utters the sentence 'Snow is white' and a French speaker utters the sentence 'La neige est blanche,' there is a clear sense in which they have both said the same thing. Moreover, given that they both intend sincerely to express their beliefs by uttering these sentences, there seems a clear sense in which they both believe the same thing. Philosophers call this thing that both have said and that both believe a *proposition*. The declarative sentences we utter and write down are said to have propositions as their linguistic meanings and to express those propositions. Two or more sentences (in the same language or in different ones) can have the same proposition as their meaning – that is, they can express the same proposition – just as different numerals (e.g., the Arabic numeral '4' and the Roman numeral 'IV') can designate the same number, namely four. Moreover, propositions are supposed to be the contents of many of our mental states, such as belief, knowledge, doubt, supposition, memory, desire, intention, and so on. Russell (1903) called these mental states "propositional attitudes."

Roles Played by Propositions

The notion of a proposition has played, and continues to play, important roles in the philosophy of logic, philosophy of language, and philosophy of mind. Three of those roles have been mentioned already: Propositions are the linguistic meanings of the sentences we utter or write down, they are the contents of our sayings when we utter or write down those sentences, and they are the contents of our thoughts. Propositions are commonly thought to have other important functions as well. They are often taken to be the "primary bearers" of truth and falsity, in the sense that the sentences we utter and the beliefs we have are true or false only derivatively in virtue of the propositions associated with them being true or false. Propositions are also said to be the primary bearers of modal properties, such as necessity, contingency, possibility, impossibility, and so on. And logical relations, such as consistency, inconsistency, and entailment, are said to hold between or among propositions.

It is a good question whether any single notion of a proposition can play all these roles at once. Sentences containing indexicals, for example, cause difficulties in this regard, for they seem to suggest that the linguistic meaning of a sentence may differ from the proposition it expresses. When I say 'I'm hungry,' and when you say 'I'm hungry,' there is a sense in which our respective sentences have the same meaning; but it also seems clear that they express different propositions, one about me and the other about you. Conversely, when I say 'I'm hungry' and you say, addressing me, 'You're hungry,' we seem to have said the same thing – that is, expressed the same proposition, a preposition about me – but uttered sentences with different meanings. In light of this, Kaplan (1989) has distinguished between the *character* (roughly, linguistic meaning) and the *content* (proposition expressed) of a sentence. Whether any single notion of a proposition can play all these different roles depends very much on what propositions are taken to be. So what then are propositions exactly? What are these entities, propositions, that we assert and believe and that are true or false and necessary or contingent?

Propositions as Abstract Entities

The history and development of the concept of the proposition are a long and complex story (Gale, 1967); but contemporary accounts derive most

Moreover, given that they both intend sincerely to express their beliefs by uttering these sentences, there seems a clear sense in which they both believe the same thing. Philosophers call this thing that both have said and that both believe a *proposition*. The declarative sentences we utter and write down are said to have propositions as their linguistic meanings and to express those propositions. Two or more sentences (in the same language or in different ones) can have the same proposition as their meaning – that is, they can express the same proposition – just as different numerals (e.g., the Arabic numeral '4' and the Roman numeral 'IV') can designate the same number, namely four. Moreover, propositions are supposed to be the contents of many of our mental states, such as belief, knowledge, doubt, supposition, memory, desire, intention, and so on. Russell (1903) called these mental states "propositional attitudes."

Roles Played by Propositions

The notion of a proposition has played, and continues to play, important roles in the philosophy of logic, philosophy of language, and philosophy of mind. Three of those roles have been mentioned already: Propositions are the linguistic meanings of the sentences we utter or write down, they are the contents of our sayings when we utter or write down those sentences, and they are the contents of our thoughts. Propositions are commonly thought to have other important functions as well. They are often taken to be the "primary bearers" of truth and falsity, in the sense that the sentences we utter and the beliefs we have are true or false only derivatively in virtue of the propositions associated with them being true or false. Propositions are also said to be the primary bearers of modal properties, such as necessity, contingency, possibility, impossibility, and so on. And logical relations, such as consistency, inconsistency, and entailment, are said to hold between or among propositions.

It is a good question whether any single notion of a proposition can play all these roles at once. Sentences containing indexicals, for example, cause difficulties in this regard, for they seem to suggest that the linguistic meaning of a sentence may differ from the proposition it expresses. When I say 'I'm hungry,' and when you say 'I'm hungry,' there is a sense in which our respective sentences have the same meaning; but it also seems clear that they express different propositions, one about me and the other about you. Conversely, when I say 'I'm hungry' and you say, addressing me, 'You're hungry,' we seem to have said the same thing – that is, expressed the same proposition, a preposition about me – but uttered sentences with different meanings. In light of this, Kaplan (1989) has distinguished between the *character* (roughly, linguistic meaning) and the *content* (proposition expressed) of a sentence. Whether any single notion of a proposition can play all these different roles depends very much on what propositions are taken to be. So what then are propositions exactly? What are these entities, propositions, that we assert and believe and that are true or false and necessary or contingent?

Propositions as Abstract Entities

The history and development of the concept of the proposition are a long and complex story (Gale, 1967); but contemporary accounts derive most

immediately from Frege's attack on psychologism and the *fin de siècle* revolt against idealism inaugurated by Russell and Moore (Frege, 1892a, 1918; Moore, 1899; Russell, 1903; Hylton, 1984). The core of this shared account is the idea that propositions are mind-independent, extralinguistic abstract entities akin to numbers, mathematical functions, and sets.

This core idea subsequently came under persistent attack by Quine (1960, 1986) who viewed propositions (and other 'intensional' entities such as properties and relations) as 'creatures of darkness' owing to the alleged lack of any criteria for individuating them, as well as their essential involvement with what Quine (1951) deemed the obscure and suspect notions of meaning and synonymy. In the service of his sparse desert ontology, Quine proposed to replace abstract propositions with concrete sentences (propositions are really just unnecessary 'shadows' of sentences anyway, to invoke Wittgenstein's metaphor) or, more accurately, with mathematical sequences of word-tokens that have been uttered or inscribed at some time (Quine, 1960). However, neither Quine's relentless critique of propositions as abstract entities nor his replacement of them with sentences has been widely accepted. Moreover, despite Quine's closely related attack on modal notions, such as necessity and possibility, the rise of modal logic and modal metaphysics continued unabated and accorded a central place to propositions construed as abstract entities. The seminal work of Kripke (1972) was instrumental in turning the tide against Quine.

Let us then turn to the most popular contemporary approaches to the nature of propositions as mind-independent, extralinguistic abstract entities. As we shall see, there has been some lack of clarity about whether theories of propositions are theories about what propositions *are*, ontologically speaking, or whether theories of propositions are theories about how they should best be represented or modeled in a formal semantic theory.

Two Approaches: Structured and Structureless Entities

Generally speaking, theories of propositions can be divided into two sorts. The first takes propositions to be certain kinds of structured entities with components standing in various relations to each other, with the structure of the entities roughly mirroring the structure of the sentences that express them. The second takes propositions to be structureless entities. The structureless approach invokes the notion of a "possible world," borrowed from the new model theory for modal logic developed in the 1950s and 1960s, known as "possible worlds semantics." A possible world is a "way things could have been." The idea is that a proposition is a set of possible worlds (the set of worlds at which the proposition is true), or equivalently, a proposition is a function (in the mathematical sense) from the set of possible worlds to the set of true values.

That the possible-worlds approach to propositions treats propositions as structureless is easily seen. Consider the sentences 'Russell is not alive and Frege is not alive' and 'It is not true that either Russell is alive or Frege is alive.' These sentences have very different structures: the first is a conjunction of two negations, and the second is a negation of a disjunction. Yet, they are true in the same possible worlds because they are logically equivalent. According to the possible-worlds approach, both sentences therefore express the same proposition.

According to the structured approach, however, these two sentences express different propositions because in the structured approach a proposition is not individuated in terms of the possible worlds in which it is true, but rather in terms of the constituents that make up the proposition. On this account, a proposition is a structured entity composed of parts, where the parts and the order of composition more or less mirror the parts and order of composition of the sentences that express the proposition.

Two Structured Approaches: Russellian and Fregean

There are, broadly speaking, two types of structured theory, the first deriving from Russell (1903) and the second from Frege (1892a), which are distinguished from each other by what they take the constituents of propositions to be. According to the Russellian (or "neo-Russellian") approach, the constituents of the propositions we assert and believe, and to which truth and falsity and modal properties belong, are the objects, properties, and relations that our assertions and beliefs are about: desks, trees, other people, and other everyday objects. According to the Fregean approach, propositional constituents are rather 'senses' or 'modes of presentation' (or concepts or 'ways of thinking') of the objects, properties, and relations that our saying and thoughts are about: modes of presentation of desks, trees, and other people. There are also combination views, according to which propositional constituents are both the things our sayings and thoughts are about and modes of presentation of those things.

On the Russellian view, propositions are identified with ordered pairs of *n* objects and an *n*-place relation: $<<x_1, \ldots, x_n>, X^n>$. The proposition that Maggie is cooking is thus identical with the ordered

pair: <Maggie, cooking>. The Fregean view identifies propositions with ordered pairs of *n* modes of presentation (of objects) and an *n*-place mode of presentation (of a relation): $<<m_1, \ldots, m_n>, M^n>$. Here, $m_1, \ldots, m_n$ are modes of presentation of $x_1, \ldots, x_n$, and M^n is a mode of presentation of X^n. The proposition that Maggie is cooking, for the Fregean, is thus the ordered pair: <mode of presentation of Maggie, mode of presentation of cooking>.

A third view, which combines Russellian and Fregean elements, has it that the propositions we believe contain both the items our beliefs are about and modes of presentation. For example, we might believe or assert 'quasisingular propositions' (Schiffer, 1978; Recanati, 1993) that contain objects, properties, and relations, as well as modes of presentation of all these things: $<<<x_1, m_1> \ldots <x_n, m_n>>, <X^n, M^n>>$. According to this view, when Tom believes Maggie is cooking, the proposition he believes is identical with the ordered pair: <<Maggie, mode of presentation of Maggie>, <cooking, mode of presentation of cooking>>. It is possible, of course, to hold that sometimes we believe one type of proposition (e.g., a Rusellian one) and sometimes we believe another type (e.g., a quasisingular one), depending on the situation and context in question. For present purposes, however, the important point is that propositional constituents are either objects, properties, and relations or modes of presentation of these things (often just called *concepts* of them – though this contemporary use of the term 'concept' should be distinguished from Frege's very different use of that term). And the propositions we believe – if there are such things – are composed out of such items in some way or another.

Ontology or Semantics?

So far, we have been speaking as if both the structureless and structured accounts of propositions were accounts of what propositions are. If this is correct, then, on the structureless account, what we assert when we assert a proposition and what we believe when we believe a proposition is a set or a function. Similarly, according to the structured accounts, to assert or to believe that Maggie is cooking is to stand in a relation to an ordered set. On the face of it, this does indeed seem very implausible (Bealer, 1998). Moreover, it is hard to understand how ordered sets could be true or false or necessary or contingent. These set-theoretic constructions just do not seem to be the kinds of things that can have the properties that propositions are supposed to have.

The structured position suffers from another problem too: *which* ordered set is the proposition that Maggie is cooking? Taking the Russellian approach as an illustration, is it <Maggie, cooking> or is it <cooking, Maggie>? There seems no way to determine (nonarbitrarily) which ordered set a certain proposition is (Bealer, 1998; Jubien, 2001). This general difficulty of reducing abstract objects, such as numbers, to sets is due to Benaceraff (1965).

In light of this, it seems best to take the structureless and structured approaches as rival ways of representing propositions in a formal semantic theory and not as accounts of what propositions are. Whether or not this is an adequate response to the foregoing objections, it is evident that, even interpreted as proposals about how to represent propositions, each approach is still not without its problems.

A Problem for the Structureless Approach

The structureless account appears to face what seems to be a devastating objection, stemming from the fact that it implies that all necessarily equivalent propositions are identical. Since the sentences 'A sister is a female sibling' and 'A brother is a male sibling' are true in all possible worlds, they express the same proposition. But, these sentences obviously have different meanings and thus seem to express different propositions. Moreover, if belief is a binary relation between a subject and a proposition, and a proposition is a set of possible worlds, then, for any necessarily equivalent propositions P and Q, if S believes P, then it follows that S believes Q. So, for example, if Maggie believes that $5 + 5 = 10$, she must then believe that arithmetic is incomplete, since both these things are true in every possible world. Valiant efforts have been made to mitigate these counterintuitive consequences (Stalnaker, 1984), but none has achieved widespread acceptance.

The very structurelessness of propositions on the possible worlds account means that propositions are not "fine grained" enough to serve as the objects of attitudes and the meanings of sentences. There are just not enough to go around on the possible worlds account. (Another approach to this problem, within the possible worlds framework, found in the work of Lewis (1972) and Montague (1974), invokes "structured intensions" and derived from Carnap's (1956) notion of "intensional isomorphism types.")

Problems for the Structured Approaches

The majority of philosophers, then, adopt a structured approach, either a Russellian one or a Fregean one. Turning first to the Russellian representation of propositions, it is evident that it is able to distinguish among necessarily equivalent propositions. The

propositions expressed by the sentences 'Sisters are female siblings' and 'Brothers are male siblings' have different constituents and are therefore distinct. So the Russellian manages to achieve a certain fineness of grain in its representation of propositions. It is a matter of controversy, however, whether his representation of propositions is fine enough. For the Russellian, the sentences 'George Eliot is a novelist' and 'Mary Anne Evans is a novelist' express the same proposition, because the parts of each sentence (e.g., the proper names and predicates) refer to (and are true of) the same things, and it is these same things that form the constituents of the propositions that each expresses. Now, whether or not we want to say that these sentences have different meanings, it has seemed to some philosophers that we do want to say that someone could believe George Eliot is a novelist without also believing that Mary Ann Evans is a novelist (even though George Eliot is Mary Ann Evans). In other words, belief content – and cognitive content more generally – seems to be extremely fine-grained. Importantly, cognitive content seems to be more fine-grained than a representation – using only the worldly objects, properties, and relations that our thoughts are about, can cope with. Since, for the Russellian, the two aforementioned sentences express the same proposition, and belief for the Russellian is a relation between a subject and a proposition, it follows that it is impossible for the two sentences 'Ralph believes that George Eliot is a novelist' and 'Ralph believes that Mary Ann Evans is a novelist' to differ in truth-value. Philosophers of a Fregean bent, however, argue that they can differ in truth-value – that such a difference in truth-value is required, for example, to explain the linguistic and nonlinguistic behaviour of agents – and that the Russellian theory must therefore be wrong. Russellians have offered systematic replies to these arguments (Salmon, 1986; Soames, 1987; Braun, 1998) but the debate remains open.

The Fregean conception of propositions exhibits perhaps the finest grain and is thus able both to distinguish among necessarily equivalent propositions (like the Russellian account but unlike the unstructured possible world account) and to allow for a difference in truth-value between the two foregoing belief sentences. Because the constituents of propositions are modes of presentation (or concepts or "senses") of the things that our beliefs are about, and modes of presentation are many-one related to these things, there will be many more modes of presentation than the things they are modes of presentation of; and so the requisite fineness of grain necessary for distinguishing between the propositions expressed by the sentences 'George Eliot is a novelist' and 'Mary Anne Evans is a novelist' will be achieved. Since these two sentences express different propositions due to their different conceptual constituents, it is possible for a person to believe the proposition expressed by one but not to believe the proposition expressed by the other.

This extra fineness of grain is bought at a certain cost, however, for it seems that the propositional grain is perhaps now too fine for propositions to play the role of the linguistic meanings of sentences. Arguably, since, for example, 'attorney' and 'lawyer' are synonyms, the sentences 'Lawyers are wealthy' and 'Attorneys are wealthy' are synonymous, that is, have the same meaning. They should therefore express the same propositions (if propositions are supposed to be the meanings of sentences). Yet, it seems possible for a person to believe that lawyers are wealthy, but to doubt whether attorneys are, indicating for the Fregean that the two sentences express different propositions. If the linguistic meanings of sentences are more coarsely grained than the cognitive contents of thoughts according to the Fregean, it is not clear whether a single thing – a proposition – can play both roles.

The Fregean theory is also incomplete in a way that the Russellian theory is not, and this takes us back to the ontological question of what propositions *are*, as opposed to the question of how best to represent them. The Russellian has a clear account of what the constituents of propositions are: the ordinary objects, properties, and relations that our thoughts and sayings are about. For the Fregean, however, the constituents of propositions are sense or modes of presentation or concepts of the things that our thoughts and sayings are about. Yet, what are these modes of presentation, these senses? All attempts to say what they are have been subjected to powerful and sustained criticism, and for this reason it is not clear whether the Fregean theory can ever be completed (Schiffer, 2003).

However, just because the Russellian has an account of what propositional constituents are does not mean that the Russellian theory is complete. For the Russellian theory suffers from the lack of any account of what binds propositional constituents together to form a unity, rather than a loose collection of unrelated parts. How is a proposition distinguished from a mere *list* of items? Frege (1892b) himself held that the key to this question was to be found in the nature of the propositional constituents themselves: At least one of them is always "incomplete" or "unsaturated" and is "completed" or "saturated" by the other constituents, which are themselves already complete or saturated. Russell (1913) struggled heroically for many years, indeed decades, to solve this

"binding" problem or "the problem of the unity of the proposition" (a problem first stated by Plato in *The sophist*) without ultimate success. Contemporary Russellians, however, have been more concerned with the construction of formal semantic theories that invoke model-theoretic representations of propositions than with the metaphysical question of what binds or glues propositional constituents together into a propositional unity. This difficult and ancient question is once again beginning to receive the attention it deserves (Gaskin, 1995; King, 1995; Jubien, 2001; Gibson, 2004).

Propp, Vladimir Iakovlevich (1895–1970)

M Toolan, University of Birmingham, Birmingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Propp was a Russian folklorist and literary formalist, whose monograph *The morphology of the folktale* (originally published in Russian in 1928, the English version only appearing in 1958) led him to be acclaimed as one of the pioneers of structuralist analytical methods applied to texts, alongside Lévi-Strauss (*see* **Levi-Strauss, Claude (b. 1908)**) and Jakobson (*see* **Jakobson, Roman (1896–1982)**). By adaptive application of methods more familiar in distributionalist linguistics, Propp sought to identify the elemental constituents, and the variant means of their combination, of a corpus of 115 Russian folktales. What emerges is a grammar of the folktale, in which Propp's counterparts of the VP and NP are event and character. He isolates just 31 fundamental, action-developing events (called 'functions') in the tales, notwithstanding the fact that those core events might have rather different surface realizations in different stories. For example, his function no. 14 is 'the hero acquires the use of a magical agent,' but many different things in different tales might constitute 'the hero,' 'a magical agent,' and the process of acquiring. Furthermore, while different tales contain any number of the 31 functions, their order of occurrence, in all tales, was unvaried. The functions operate upon just 7 basic recurring character roles ('villain,' 'hero,' 'helper,' 'princess,' etc.); these roles may be combined in a single individual (e.g., one person may be both 'helper' and 'princess'), or a particular role might be filled by several individuals (a gang of thieves fills the 'villain' role). The entire project is avowedly reductive and oriented to plot alone (it is silent on questions of characterization, tone, style, symbolism, and so on). It has given rise to a number of computerized story- and fairytale-generators and to many critical applications to film. Some of the particular interest in the *Morphology* lies in the fact that it was one of the earliest systematic demonstrations of what could be done with a corpus of actually occurring texts, using resolutely structuralist-distributionalist methods; it points both to the achievements and the limitations of that kind of abstracting formalism applied to material so laden with cultural and psychological meaning as the folktale. In these and other respects (the possibility of event-sequence transformations; the merits of abstraction and generalization), reactions to the *Morphology* provide striking parallels to some of the critical reception given to transformational-generative grammar in the 1960s.

Prosodic Aspects of Speech and Language

D J Hirst, Université de Provence, Aix-en-Provence, France

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A speech sound, just like any sound in general, can be characterized by three characteristics:

- its quality or timbre
- its length
- its loudness

If the sound is periodic (i.e., voiced), then it can also be characterized by:

- its pitch height

These four characteristics refer to auditory impressions, which can be related to the three acoustic dimensions:

- time
- intensity
- frequency

The three acoustic dimensions can be visualized by means of a spectrogram, as in Figure 1, which shows a spectrogram for the English word far /fa:/. All acoustic analyses in this article were obtained by means of the excellent free software Praat (Boersma and Weenink, 1992–2005).

Figure 1 Spectrogram of the English word 'far' /faː/.

The spectrogram is a three-dimensional representation of a sound showing the distribution of energy (on a scale going from white to black) at different frequencies (vertical scale) as a function of time (horizontal scale).

These acoustic dimensions can be used in turn to define four parameters, which are essentially responsible for the four auditory characteristics listed above:

- Voice quality or timbre is related to the distribution of energy in the spectrum.
- Length is related to the duration in seconds (s) of the sound.
- Loudness is related to the intensity in decibels (dB) of the sound.
- Pitch, for voiced sounds, is related to the fundamental frequency in periods per second or Hertz (Hz).

In Figure 1, the consonant /f/ is unvoiced and consequently has no fundamental frequency, whereas the vowel /aː/ is voiced and has a measurable fundamental frequency.

Of these four parameters, the spectral characteristics are the most complex and naturally are exploited the most in creating lexical items in different languages. Thus the difference between *four* /fɔː/ and *far* /faː/ comes from a different distribution of energy in the spectrum of the vowel, while the difference between *far* /faː/ and *car* /kaː/ comes from a different distribution of energy in the spectrum of the consonant (Figure 2).

The other three parameters – duration, fundamental frequency, and intensity – are often referred to as prosodic or suprasegmental parameters. All languages make use of these parameters for nonlexical purposes, characterizing the way in which the individual words are combined into larger speech units and the relative prominence of the different words as well as more paralinguistic characteristics related to the expression of affect.

The prosodic parameters also contribute to the lexical identity of words in many languages.

Duration is exploited through the lexical characteristic of quantity in languages like Finnish where /taka/ /takka/ /taakka/ /takaa/ /takkaa/ /taakkaa/ all have distinct meanings (back-, fireplace, burden, followed by the partitive case for the same three words) (Figure 3).

Fundamental frequency is exploited through the lexical characteristic of tone in languages such as Vietnamese, where /ma/ with: (a) high level tone, (b) rising tone, (c) glottalized rising tone, (d) low falling tone, (e) falling-rising tone, and (f) glottalized falling tone all have distinct meanings ('ghost', 'mother', 'horse', 'maize', 'tomb', 'young rice plant', respectively). It is also exploited through the characteristic of pitch accent in languages such as Japanese where /'hanadesu/, /ha'nadesu/ and /hanadesu/ or /'hasidesu/, /ha'sidesu/, and /hasidesu/ all have distinct meanings ('it's Hana' [= name], 'it's a flower', 'it's a nose', 'it's chopsticks', 'it's a bridge' and 'it's an edge', respectively).

Intensity is related to the lexical characteristic of stress in languages such as Russian where /'muka/ and /mu'ka/ have different meanings ('torment' and 'flour', respectively).

The relationship between the auditory characteristics and the acoustic parameters is, however, not quite so simple as the preceding description might seem to imply.

Quantity often entails spectral characteristics as well as mere duration. English is a good example of this since what can be, and often has been, described as a phonological distinction between long and short vowels in English (i.e., /iː/ vs /ɪ/, /uː/ vs /ʊ/) involves in most dialects a difference in voice quality so that the 'long' vowels might be transcribed more narrowly as diphthongs /ɪi/ and /ʊu/, as can be seen from the spectrogram of the phrase 'two weeks' in Figure 4, where the diphthongued nature of the two 'long' vowels /uː/ and /iː/ is clearly visible.

Tonal distinctions can also be more complex than simple variations of fundamental frequency and often combine differences in voice quality such as breathy or creaky voice as well as intensity differences. Thus, the third of the six tones in Vietnamese listed above is like a glottalized version of the second one (Figure 5).

Stress, finally, is a complex combination of all four parameters since stressed vowels are generally more intense, longer, less centralized, and have a distinctive fundamental frequency pattern. In the Russian words /'doma/ (house [accusative singular]) and /da'ma/ (house [nominative plural]), both are written 'дома', but when the stress is on the second syllable

Figure 2 Spectrograms of the words 'four' /fɔ:/, 'far' /fa:/ and 'car' /ka:/.

Figure 3 'Taka', 'takka', 'taakka', 'takaa', 'takkaa', 'taakkaa'. Illustrating distinctive quantity for vowels and consonants in Finnish (see text).

this brings about a change of vowel quality of the first vowel that is an essential cue to the place of stress.

The way in which prosodic characteristics have been lexicalized in different languages is consequently not a simple one-to-one mapping between the three prosodic parameters of length, pitch, and loudness and the phonological categories of quantity, tone, and accent.

The rest of this article will be concerned with the nonlexical characteristics of the prosodic parameters of length, pitch, and loudness.

Length

Many languages do not possess any lexical distinction of quantity. This is the case with modern standard French, even though some conservative speakers today maintain what was once a more productive distinction between long and short vowels (as in: *mètre* /mɛtʁ/ 'meter' vs. *maître* /mɛːtʁ/ 'master'). Even these speakers, however, will tend to resort to the short vowel in words like *naître* or *paître* where there is no minimal pair to maintain the opposition. Even in

Figure 4 Spectrogram of the English phrase 'two weeks' /tu:wi:ks/ showing the diphthonged nature of the vowels /u:/ and /i:/.

Figure 5 Rising tone and glottalized rising tone in Vietnamese: má 'mother' and mã 'horse'. The figure displays (top) the fundamental frequency (F0) expressed in Hz and (below) the waveform for each word.

languages like French, which do not possess lexical distinctions of quantity, it is possible to find distinctive differences of quantity in connected speech. Thus, it is possible to find in French connected speech minimal pairs for quantity both for consonants:

Il part tôt. /ilpaʁto/ (he leaves early)
vs.
Ils partent tôt. /ilpaʁtto/ (they leave early)

and for vowels:

Il a battu le chien. /ilabatyləʃjɛ̃/ (he beat the dog)
vs.
Il a abattu le chien. /ilaabatyləʃjɛ̃/ (he killed the dog)

Although these 'long' consonants and vowels in French are represented here as a sequence of two consonants or two vowels, there is nothing phonetically to distinguish them from the same sequence of phones with a 'long' consonant or vowel so that they could equally well be transcribed: [ilpaʁt:o] and [ila:batyləʃjɛ̃].

Intrinsic Duration

According to Klatt (1987), the nature of the phoneme is the biggest single factor influencing segmental duration. This has an effect in two ways.

First, the mean duration of /w/, for example, may be intrinsically only half the length of, say, /ʃ/.

Secondly, some phonemes are intrinsically more compressible than others. Different compressibility has been treated by expressing the variability in terms of a relation between an intrinsic duration and a minimum duration, as suggested by Klatt (1987). Another approach (Campbell, 1992) has been to normalize duration, by subtracting the mean of the phoneme class and dividing the result by the standard deviation of the same class. Since such normalization procedures assume that the measurements are normally distributed, it is often the logarithmic values of duration that are used, since it has been shown that the log distribution of segmental durations is closer to a normal distribution than is the raw distribution in milliseconds.

Rhythm: Stress Timing, Syllable Timing, and Mora Timing

Different distributions of the duration of individual speech sounds can give rise to different auditory impressions of rhythm in different languages. In particular it has been claimed that languages exhibit a property of isochrony, which can be defined as the organization of speech into chunks that are perceived to be of equal, or at least equivalent, duration.

Pike (1945) suggested that two types of rhythm can be found in languages: syllable-timed rhythm, where syllables give the impression of being of equivalent duration, and stress-timed rhythm, where it is the stressed syllables that are perceived as occurring at regular intervals, whatever the number of intervening unstressed syllables. Abercrombie (1964) claimed that this corresponds to a universal typological distinction and that all languages can be classified into one of two rhythmic classes: syllable-timed languages (such as English, Russian, and Arabic) and stress-timed languages (such as French, Telugu, and Yoruba). Ladefoged (1975) proposed to add a third rhythmic class, that of mora-timed languages, for languages such as Japanese and Tamil where the

rhythm is determined by units smaller than the syllable, known as morae, something like short beats in music. In Japanese, for example, open syllables with short vowels, like /na/ or /i/ are said to contain one mora, whereas closed syllables like /nan/ or syllables with long vowels like /i:/ are said to contain two morae. The following minimal pairs are distinguished by the fact that the second expression in each case contains one mora more than the first:

nado (and others)	nando (how many times)
shite-imasu (I'm doing it)	shitte-imasu (I know)
ie (house)	iie (no)

Almost embarrassingly, however, this neat typological distinction of three rhythmic classes has not stood up very well to empirical investigation.

Among a number of experimental studies questioning the validity of this typological distinction, Roach (1982), for example, measured the standard deviation of syllable durations for about 2 minutes of spontaneous unscripted recordings by speakers of each of the six languages mentioned above and found no evidence that the languages classified as stress-timed exhibited any more variability of syllable duration than the languages classified as syllable-timed. He also measured the duration of interstress intervals for the six speakers (measuring the duration from the onset of each syllable that appeared to be stressed until the onset of the next one within the same intonation unit). This duration was expressed as a percentage of the duration of the whole intonation unit to compensate for any possible effects of change of tempo (see below). The results of this, contrary to what would be predicted by the typological distinction, showed – if anything – a greater variability in the duration of the interstress intervals for the so-called stress-timed languages than for the so-called syllable-timed languages. There was, furthermore, no evidence that the duration of interstress intervals was any less correlated with the number of syllables that they contained for the stress-timed languages than for the syllable-timed languages.

A recent study (Ramus *et al.*, 1999) built on the fact that psycholinguistic studies had shown that young infants, including newborns, can discriminate between sentences taken from their own language and sentences taken from a language belonging to a different rhythmic class, but not between sentences from languages of different rhythmic classes.

The authors proceeded to attempt to identify what they claimed were "correlates of linguistic rhythm in the speech signal." Using recordings of five different sentences spoken by four speakers for each language, they first segmented the sentences into 'vocalic intervals' and 'consonantal intervals,' defined as portions

Figure 6 Duration of vocalic intervals as percentage of duration of sentence (%V) and standard deviation of consonantal intervals (ΔC) for eight languages: English (EN), Dutch (DU) and Polish (PO), Spanish (SP), Italian (IT), French (FR) and Catalan (CA), and Japanese (JA), showing how the languages group into stress-timed, syllable-timed, and mora-timed rhythmic classes. Figure from Ramus *et al.*, 1999.

of the speech signal containing, respectively, sequences of only vowels or only consonants. Thus, a phrase such as 'next Tuesday on' /nekstju:zdeɪɐn/ would be segmented into alternating consonantal and vocalic intervals as follows: /n – e – kstj – u: – zd – eɪɐ-n/. They then calculated two parameters, %V, the sum of the durations of the vocalic intervals expressed as a percentage of the total duration of the sentence; and ΔC, the standard deviation of the consonantal intervals within each sentence. They showed that these two parameters made it possible to separate the three rhythmic classes quite well, as can be seen from Figure 6.

It must, however, be said that the claim that this analysis reflects correlates of linguistic rhythm 'in the speech signal' is slightly misleading. The measurements rely on a prior linguistic segmentation of the signal into phonemes and a classification of the phonemes into consonants and vowels. Neither of these operations are purely acoustic. It might then be wondered whether the parameters represented in Figure 6 are an image of the rhythm of the utterances themselves, or of the rhythm of the **text** of the utterances, as had been suggested by Dauer (1983). Indeed it seems likely that a similar discrimination can be obtained if, instead of the duration of each vocalic or consonantal interval, we measure simply the number of phonemes in that interval, as illustrated in Figure 7, which shows the number of vowel phonemes expressed as a percentage of the total number of phonemes and the standard deviation of the number of consonant phonemes in each consonant interval for five comparable sentences in English and French.

Figure 7 Percentage of vowel phonemes (%V) and standard deviation (ΔC) of number of consonants in each consonantal interval for five sentences in English (E) and French (F).

This figure shows that English and French seem fairly well distinguished on the basis of the phonological structure of utterances without any reference to the speech signal. It seems possible, then, that what Ramus *et al.*'s metric is doing is little more than counting the relative number of consonants and vowels in the different languages. A lower percentage of English phonemes are vowels than in French and the number of consonants in consonantal intervals is more variable in English than in French.

Of course, Ramus *et al.*'s claim is precisely that children derive such information about the phonological structure of their native language from the acoustic data.

For other recent attempts to define an objective metric reflecting rhythmic classes, including work trying to establish such metrics directly from the acoustic signal, see papers in the special session on *Prosody and Linguistic Typology* in Bel and Marlien, 2002.

Suprasyllabic Prosodic Constituents in English

To illustrate the complexity of the study of rhythmic structure, this section will be essentially devoted to a number of analyses of rhythm in English, although presumably all the questions raised here could be applied to the study of the rhythmic structure of any language.

Abercrombie (1964) suggested that stressed syllables, in stress-timed languages, joined with any following unstressed syllables to form a rhythmic unit that he called the foot. This is sometimes referred to today as the stress-foot to distinguish it from the rather different concept of metrical foot used in autosegmental and metrical phonology. In the rest of this section, reference to the foot will be to Abercrombie's definition: each foot starts with a stress and contains everything up to, but not including, the next stress (Abercrombie, 1964: 217).

Abercrombie made two strong and, in fact, quite controversial claims about the foot. Firstly, he stated specifically that the foot does not take into account word boundaries: a phrase such as 'It's almost impossible' would be grouped into feet as follows

/ ɪts | ɔ:lməʊstɪm | pɒsɪbəl /

where (|) corresponds to the foot boundary; the initial phonemes /ɪts/, under this analysis, do not belong to a foot.

The second claim made by Abercrombie was that the relative quantity of syllables in a foot in English is not directly dependent on either vowel quantity or on stress. Abercrombie distinguished three types of disyllabic feet. In the first (short-long, or type A) found in words such as *shilling* or *never*, the stressed syllable (with a short vowel and no final consonant) is metrically shorter than the unstressed syllable. In the second type (equal-equal, or type B), found in words such as *greater*, *firmly*, or *matches*, the stressed syllable (with a long vowel and/or final consonant) is metrically of equivalent length to that of the unstressed syllable. Abercrombie finally distinguished a third type, (long-short, or type C) in expressions such as *Grey to*, *tea for*, which owes the short nature of the unstressed syllable to a word boundary occurring before it.

This second claim seems to be in complete disagreement with most writers who have worked on speech synthesis in a number of different languages and who take it as an axiom that phonemes in stressed syllables are intrinsically longer than phonemes in unstressed syllables.

Klatt (1987), for example, included among his 11 rules for predicting segmental duration a rule of unstressed shortening, which stated that unstressed segments are considerably shorter and more compressible than stressed segments. Similar claims have been implemented into a considerable number of speech synthesis systems for different languages, as summarized in Campbell (1992) for example, as well as in a number of papers in Benoit *et al.* (1991) and van Santen *et al.* (1997).

Other writers have claimed that word boundaries play an important role in the determination of the rhythmic structure of utterances. Jassem (1952), for example, proposed a narrow rhythm unit for English, which, just like the foot, starts with a stress, but, unlike the foot, ends at the following word boundary. Any syllables not part of a narrow rhythm unit, according to Jassem, form an anacrusis, which is pronounced "as quickly as possible." The phrase 'It's

almost impossible' in Jassem's model has a structure like:

/ (ɪts) | ɔ:lməʊst (ɪm) | pɒsɪbəl /

where the phonemes in parentheses are those of the anacrusis.

Like Abercrombie, Jassem suggested that the duration of phones is not directly affected by the stressed/unstressed nature of the syllable, but that the duration of the unit is spread out more or less equally among the phones, with a certain degree of compression so that a unit containing six phonemes, for example, would be longer than one with only three phones but not twice as long.

Campbell (1992) presented a model in which the duration of phones is determined by a two-level hierarchical rhythmic structure consisting of feet and syllables. In this model, the duration of the syllable is determined by the number of syllables in the foot and the duration of the phoneme by the number of phonemes in the syllable. Contrary to both Jassem and Abercrombie, Campbell also claimed that stressed syllables are intrinsically longer than unstressed syllables.

Recent work carried out in our research group (Bouzon and Hirst, 2004; Bouzon, 2004) has attempted to test some of these different hypotheses on a large (5.5-hour) corpus of spoken British English (Auran *et al.*, 2004). In order to compare results for different phonemes, following Campbell, the raw phoneme duration was normalized using the mean and standard deviation of each phoneme class. The raw phone duration was replaced by the z-score calculated as

$$z_p = \left[d_p - \mu_p\right]/\sigma_p$$

where d_p is the raw duration of the phone, μ_p is the mean duration, and σ_p the standard deviation for the phoneme class.

Results from this analysis seem to show that, as predicted by Jassem, word boundaries **do** play an important role in the rhythmic structure of English. They further suggest that, contrary to Campbell's findings, there is no specific compression at the level of the syllable so that all other things being equal, a syllable containing four phonemes will be twice as long as a syllable containing only two. The most surprising result was the confirmation of Jassem's prediction that once we know whether a given phone belongs to an anacrusis or to a narrow rhythm unit, and in the latter case once we know the number of phones in that unit, the fact that the phone occurs in a stressed or an unstressed syllable has no specific effect on its duration.

Work on rhythmic structure across languages is clearly a promising field for future research, particularly with the possibility of taking into account large corpora of authentic speech data.

Tempo

At an even higher level than that of the rhythmic unit or the foot, changes in relative duration of speech segments can be observed corresponding to longer-term portions of utterances. In this case, such changes are usually referred to as changes in tempo, or speaking rate.

One obvious question about tempo that springs to mind is: Are some languages spoken more quickly than others?

Roach (1998) addressed precisely this question. Many listeners seem to have fairly consistent intuitions that, for example, Italian and French are spoken faster than, say, Dutch and German. Roach's study gave positive results for this when the speaking rate was measured in syllables per second. When the same data were measured using phonemes per second, however, the differences between languages turned out to be nonsignificant. The apparent faster speaking rate of Italian and French simply reflects the fact that Italian and French syllables have, on average, fewer phonemes than German or Dutch syllables.

It is interesting to compare this result with that of a study by Pfitzinger (1998) on the perception of German rhythm by native speakers. Subjects were asked to classify a number of utterances from fastest to slowest. A fairly high agreement was found across subjects. The resulting classification was well correlated with both phonemes per second and syllables per second and an even better correlation was found by taking into account both rates. An explanation of this could perhaps be that an increase in phones per second must correspond to a higher degree of activity on the part of the speaker. By contrast, since there is ample evidence that vowel onsets correspond to a particularly salient feature of a syllable, an increase in the number of vowel onsets per second is likely to produce an impression of greater speed. This asymmetry between production and perception is perhaps the explanation for listeners' judgments concerning the relative tempo of the different languages reported above.

Loudness

The perceived loudness of a speech signal is obviously correlated with its intensity, which is not difficult to measure. Of all the prosodic parameters, however, loudness is probably the least well understood and certainly, for this reason, the least researched. The

Figure 8 A sequence of nonsense syllables /'mama'mama'mama . . ./ (18 syllables in all) pronounced with the speaker at first facing the microphone and then turning round in a complete circle.

main reason for this is that the intensity of sounds varies considerably as a function of the distance between the microphone and the sound source. This is usually counteracted in experimental subjects by placing the subjects at a fixed distance from the microphone and asking them not to move too much. In normal everyday speech, of course, this is not possible and there are consequently considerable fluctuations in the intensity of the signal that reaches a listener's ears. To illustrate this, Figure 8 shows the fundamental frequency, intensity, and wave form of a sequence of nonsense syllables /'**mama**'**mama**'-**mama** . . ./ (18 syllables in all) pronounced while the speaker starts off facing the microphone and then turns around in a complete circle so that in the middle of the recording he is completely turning his back to the microphone.

As can be seen from this figure, the fact that the speaker turns his back to the microphone has no effect on the detected F0. The effect on the intensity, however, is quite drastic, with a drop of more than 10 dBs from the first stressed syllable to the sixth. This drop is considerably more than the difference between the stressed and the unstressed syllables. Since speakers in everyday life do move around while they are speaking and do even turn away from their listeners, it is obvious that raw intensity by itself is not a very robust cue for loudness. Facts like these led many phoneticians, such as Fry (1958) and Bolinger (1958), to conclude that the major cue for accent in English was pitch excursion, with duration as a secondary cue, and that intensity played only a very minor role. More recent work (Sluijter, 1995) has shown that stressed vs. unstressed syllables are marked not by a global increase in intensity but by an increase in the intensity of higher frequencies. Since the ratio of the intensity of higher vs. lower frequencies is a relative measure, this would remain robust despite variation of global intensity such as that illustrated in Figure 8. This effect, variously known as spectral tilt, spectral balance, or spectral emphasis, obviously opens new perspectives for the analysis of loudness as a distinctive characteristic of speech. There is, however, as yet no generally accepted standard measure of this characteristic, although various measures that have been proposed are the difference

between the first harmonic (H1) and the third formant (A3) or the difference between the first and second harmonics (H2–H1); for a recent overview of these measures, see Heldner (2003).

Pitch

Besides its role in lexical categorization by distinctive tones and pitch accents, the pitch height of voiced speech sounds seems to be fairly universally used to indicate a rather large number of characteristics of speech. These include, on the more linguistic end of the scale, categories of prominence (focus and emphasis) and syntactic or semantic grouping. The relation of prosody to grouping, despite considerable discussion, is still somewhat controversial. For some authors, there is a clear relation between prosodic boundaries and syntactic structure since the boundaries regularly occur at the left edge of syntactic constituents. For others, the boundaries are taken to delimit semantic rather than syntactic units (Hirst, 1998).

On the more pragmatic end of the scale, pitch is used to communicate utterance modality i.e., statements vs. questions, finality vs. nonfinality, etc., although once again there is considerable disagreement among authors as to the syntactic, semantic, or pragmatic nature of such distinctions. The nearly universal tendency to associate final lowering of pitch with statements and final raising of pitch with questions is contradicted by a number of languages that do not systematically use a final rise for questions (e.g., Danish, Finnish, and Western Arabic; Hirst and Di Cristo, 1998), although in such languages, questions are often associated with a global raising of pitch or an incomplete final lowering. There are, furthermore, languages and dialects where a default declarative utterance is regularly produced with a final rise. These include certain varieties of Scandinavian languages as well as a number of urban dialects of the northern United Kingdom (e.g. Newcastle, Glasgow, Belfast, Liverpool, Manchester, etc.). There is, however, to my knowledge, no language that has been reported as systematically associating a final fall with a question and a final rise with a statement.

Another fairly universal tendency is to associate a gradual lowering of pitch with cohesion and conversely a raising or resetting of pitch with a change of topic or a syntactic/semantic boundary of some kind. In many phonetic studies, this lowering effect has been referred to in general as declination. It has been argued, however (Connell and Ladd, 1990) that there are several different processes that have been put together under the same label.

The first of these is a phonologically conditioned lowering, which has traditionally been called downdrift by linguists working particularly on African tone languages (Hyman, 1975). In Bambara (Mali), for example (Bird *et al.*, 1977), the second syllable with a high tone in an utterance will normally be pronounced on a slightly lower pitch than the first when they are separated by a syllable with low tone. Thus in:

sìsé nà kúmà
'Sisse is going to talk.'

the syllable /kú/ will be slightly lower than the syllable /sé/. In fact, if the second high tone is pronounced on the same level as the first, this will give the impression of a prosodic boundary as in:

sìsé | nà kúmà
'Sisse! Come and talk!'

That this lowering is not simply a continuous function of time can be seen from the fact that a sequence of syllables with high tones like:

jírí té
'it's not a tree'

will all be pronounced on more or less the same level.

A phonologically distinctive lowering, traditionally called downstep, can also be illustrated by the following from the same language:

jírí ↓té
'it's not the tree'

where the slight lowering of the final syllable – indicated here by the symbol (↓) – serves as a definite marker for the preceding noun.

Many phonologists make a clear distinction between conditioned lowering, or downdrift, where there is an intervening low tone, and distinctive lowering, or downstep, where there is no intervening low tone. Others prefer to call both types of lowering downstep.

A third type of lowering is that of final lowering where the final part of an intonation unit is lowered more than would be expected from normal processes of downdrifting.

The fourth type of lowering, called declination, is a systematic continuous function of time and which, unlike the other types, is not triggered by any particular tonal configuration or context. This temporal declination is often assumed to be related to physiological constraints and can be best observed in languages like English that can have a falling pitch on a nonfinal syllable followed by a number of syllables on a low pitch.

Measuring F0

The relation of pitch to acoustic properties is relatively straightforward since the pitch height of a speech sound is rather directly related to the frequency of vibration of the vocal folds. This is traditionally measured on a linear scale as the number of periods per second, or Hertz (Hz). Many phoneticians, however, prefer to use a logarithmic scale that captures the broad generalization known as the Weber-Fechner law, which states that the magnitude of a sensation is directly proportional to the logarithm of the magnitude of the stimulus. This is the reason why many studies use a scale of semi-tones (sts) since a semi-tone corresponds approximately to a just noticeable difference in the pitch of two adjacent speech sounds and it is of course familiar as the interval between two adjacent keys on a piano (including both black and white keys). A more appropriate unit, less tied to the cultural tradition of Western classical music might have been the octave (8ve) subdivided, like all scientific units, into thousandths or millioctaves, (m8ves). The formula for calculating octaves from Hertz is:

$$8\text{ve} = \log2(\text{Hz})$$

Octaves can be simply converted into semitones or millioctaves by multiplying by 12 or 1000, respectively.

A number of other scales have been proposed at various times as being more appropriate for measuring the frequencies of speech sounds. These include the Mel scale, the Bark scale, and more recently the equivalent rectangular bandwidth (ERB) scale (Hermes and van Gestel, 1991). All these can be directly calculated by the Praat program.

If we plot these scales against the linear scale, in a range from 50 to 500 Hz, we obtain the curves shown in Figure 9. As can be seen, the scales can be ordered as follows:

$$\log(\text{Hz}) > \text{ERB}(\text{Hz}) > \text{Bark}(\text{Hz}) > \text{Mel}(\text{Hz}) > \text{Hz}$$

The ERB scale is consequently intermediate between a linear and a log scale but closer to the log scale than either the Bark or Mel scales.

Quantitative Models of Pitch

The search for an appropriate scale for measuring fundamental frequency has been one part of a systematic attempt, in particular by researchers from Holland ('t Hart *et al.*, 1990), to develop a model of the way in which pitch is **perceived**. This was done by stylizing raw fundamental frequency patterns as a sequence of straight lines, such that when the stylized frequency is used to resynthesize the utterance, the result is judged to be perceptually equivalent to the original intonation pattern.

Figure 9 Comparison of different scales for measuring the pitch of speech sounds. The linear frequency (horizontal axis) is compared to four other scales (vertical axis), scaled so that the beginning and end of the curves correspond to 50 and 500 Hz, respectively. The top curve corresponds to the log of the Hz, followed by the ERB, Bark, and Mel transforms. The lowest scale is the linear scale in Hertz.

Another approach to modeling pitch has been to attempt to model the way in which pitch is **produced** by speakers. In particular, work by Fujisaki and his colleagues has applied a model of pitch production (Fujisaki, 1983) to a large number of languages, including several tone languages, analyzing a fundamental frequency curve as consisting of a basic phrase curve with a sequence of accent curves superimposed on it.

A third approach has been to develop acoustic models that are neither directly models of speech perception nor of speech production, but which are compatible with both. In the Momel algorithm developed in our laboratory in Aix-en-Provence (Hirst *et al.*, 2000), the raw fundamental frequency curve is factored into two components, a micro-prosodic component, which is conditioned by the segmental nature of the individual speech sounds, and a macro-prosodic component, which corresponds to the underlying laryngeal gesture. This corresponds to the observation (Nooteboom, 1997) that we do not perceive the observable discontinuities of raw pitch patterns unless they are longer than about 200 ms, "as if human perception unconsciously bridges the silent gap by filling in the missing part of the pitch contour" (Nooteboom, 1997: 644). Similarly, the irregularities introduced by the voiced portions of the microprosodic component (i.e., during the voiced consonants) are not perceived as contributing *per se* to the overall pitch pattern of the utterance.

The macroprosodic component is modeled as a sequence of target points linked by a quadratic spline

Figure 10 Fundamental frequency curve (top panel) of the sentence 'Every Thursday I have a programme here on Radio 4 called ''Employment'' '. In the bottom panel, the same curve is displayed together with the smooth continuous modeled curve calculated by the Momel algorithm.

function, which basically is the simplest mathematical function that meets the two criteria of continuity and smoothness observed when, for example, a speaker hums the intonation of an utterance or reiterates the pattern on a sequence of sonorant segments such as *mamama* or *lalala*.

Figure 10 illustrates the analysis of a sentence in English using the Momel algorithm.

Acknowledgments

I would like to thank colleagues who kindly supplied me with sound files to illustrate this chapter: Martti Vainno (Finnish), Pierre Durand (French), Nobuaki Minematsu (Japanese), Irina Nesterenko (Russian) Tranh Nguyen (Vietnamese). The English examples are taken from the Aix-Marsec and Eurom1 corpora.

Prosodic Cues of Discourse Units

Discourse Units in Scripted vs. Unscripted Speech

Before addressing the question of which prosodic features cue which units in spoken discourse, it is necessary to determine whether we are talking about scripted or unscripted discourse. Scripted, or preformed, discourse is prototypically monologic, one-way communication, whereas unscripted discourse is more likely to be produced spontaneously, often in interactive communication. Depending on the circumstances in which discourse is produced and processed, the nature of speakers' units varies dramatically. In scripted discourse, of which the lecture, public speech, and news broadcast are prototypical, the speaker is animating a text that has been drafted in advance. Although an occasional off-the-cuff remark may be inserted, this kind of discourse is typically cast in a written-language mode intended to be read aloud. Consequently, its textual units are units of written grammar (e.g., the sentence and the paragraph). When read aloud, these grammatical units are often homomorphic with prosodic units such as the 'spoken sentence' or the 'spoken paragraph' – units created by characteristic patterns of pitch, loudness, and timing (including pause). In performance, skilled readers may depart from a one-to-one correspondence between printed and spoken units for rhetorical or aesthetic reasons. With unskilled readers, however, such departures are more likely to result from improperly learned 'reading intonation.' Children must be taught how to intone texts meaningfully. The skill does not come naturally nor are all readers equally adept at rendering a written text orally (Esser, 1988).

Unscripted discourse, in contrast (if we take everyday conversation as its prototype), is produced as part of a two-way communicative event in which several parties (two or more) take turns speaking. The units of unscripted discourse revolve around the turn, flexibly constructed so as to be adaptable to the contingencies of interaction (Selting, 2000). They involve speech produced and processed online in a spoken-language mode, and prosodic features including

Prosodic Cues of Discourse Units

E Couper-Kuhlen, University of Potsdam, Potsdam, Germany

Discourse Units in Scripted vs. Unscripted Speech

Before addressing the question of which prosodic features cue which units in spoken discourse, it is necessary to determine whether we are talking about scripted or unscripted discourse. Scripted, or preformed, discourse is prototypically monologic, one-way communication, whereas unscripted discourse is more likely to be produced spontaneously, often in interactive communication. Depending on the circumstances in which discourse is produced and processed, the nature of speakers' units varies dramatically. In scripted discourse, of which the lecture, public speech, and news broadcast are prototypical, the speaker is animating a text that has been drafted in advance. Although an occasional off-the-cuff remark may be inserted, this kind of discourse is typically cast in a written-language mode intended to be read aloud. Consequently, its textual units are units of written grammar (e.g., the sentence and the paragraph). When read aloud, these grammatical units are often homomorphic with prosodic units such as the 'spoken sentence' or the 'spoken paragraph' – units created by characteristic patterns of pitch, loudness, and timing (including pause). In performance, skilled readers may depart from a one-to-one correspondence between printed and spoken units for rhetorical or aesthetic reasons. With unskilled readers, however, such departures are more likely to result from improperly learned 'reading intonation.' Children must be taught how to intone texts meaningfully. The skill does not come naturally nor are all readers equally adept at rendering a written text orally (Esser, 1988).

Unscripted discourse, in contrast (if we take everyday conversation as its prototype), is produced as part of a two-way communicative event in which several parties (two or more) take turns speaking. The units of unscripted discourse revolve around the turn, flexibly constructed so as to be adaptable to the contingencies of interaction (Selting, 2000). They involve speech produced and processed online in a spoken-language mode, and prosodic features including

pitch, loudness, and timing (rhythm and speech rate) are an integral part of their formatting. The prosodic features used in everyday conversation are not consciously taught but are instead acquired along with communicative competence (Couper-Kuhlen and Selting, 1996a). In contrast to 'reading intonation,' for which there is generally a single acknowledged standard, prosodic formatting in unscripted discourse displays variety-specific features.

Scripted Speech or Read-Aloud Texts

The Spoken Sentence

The spoken sentence, despite its name, is not in the first instance a syntactic unit but rather a prosodic one. Its beginning is signaled by high pitch, or a high tone, on the first accented syllable of an intonation phrase and its end by a falling tone starting on or from the last accented syllable of an intonation phrase and reaching a low point in the speaker's voice range (Wichmann, 2000). Canonically, the first and last accents in the spoken sentence, together with other intervening accents, form a pitch line that gradually descends, or declines, throughout the unit (Couper-Kuhlen, 1986). A similar line of declination has been postulated for amplitude (Laver, 1994). Spoken sentences may consist of one or more intonation phrases or tone groups; if there are several, the groups must be linked by a single declination line for pitch and amplitude.

Spoken sentences do not always correspond to the syntactic/orthographic sentence. The same prosodic patterns are used to render titles, headings, and often, in news broadcasts, the first noun phrase of a news item. Moreover, final adverbials and other nonfocal information in the sentence may be articulated with utterance-final rises, and falls-to-low may occur within a sentence (e.g., at the end of a main clause or at other points where the sentence could be possibly complete but is not). When spoken sentences consist of more than one intonation phrase or tone group, the groups are typically made to cohere by suppressing the height of the first accented syllable and any preceding unaccented syllables at the beginning of subsequent groups ('onset depression') (Wichmann, 2000). This tonal sandhi between the end of one group and the beginning of the next serves as an iconic cue to the cohesion that holds between the parts of the spoken sentence.

The Spoken Paragraph

Just as the written sentences of a text are, as a rule, grouped into written paragraphs, so spoken sentences tend to group into spoken paragraphs or paratones (Yule, 1980). However, whereas written paragraphs are conceptual or topical units, paratones are first and foremost prosodic in nature. Like spoken sentences, they have high pitch at the outset ('high pitch reset'), but the pitch on their first accented syllable is extra high. Any unaccented syllables before the first accent also tend to be high. The peak on the first pitch accent at the beginning of a paratone regularly comes late with respect to the core of the syllable. In extreme cases, it does not show up until the following syllable (Wichmann, 2000). The end of a paratone is cued by extra-low pitch, close to the speaker's baseline, and frequently by a noticeable pause (Couper-Kuhlen, 1986).

In addition to these boundary cues to the spoken paragraph, there is some indication that its constituent parts, the spoken sentences, are linked internally via an overriding declination line. This so-called 'supradeclination' appears to define a global envelope within which more local pitch variation – in conjunction with information structure and rhetorical text relations – occurs (Wichmann, 2000).

Unscripted Speech or Talk-in-Interaction

The Turn-Constructional Unit

Regarding the discourse units created spontaneously in talk-in-interaction, conversation analysts have argued that the smallest of these is the turn-constructional unit (TCU) (Sacks *et al.*, 1974). TCUs are grammatical constituents of varying size – word, phrase, clause, or sentence – that are used to implement communicative actions. Whether a given word is a lexical TCU or is part of a phrasal, clausal, or sentential TCU is cued by its prosodic formatting. If it forms a prosodic contour of its own – an intonation phrase or tone group – it is likely to be a TCU; if it does not, it is more likely to be a fragment of one. Occasionally, sentential constructions are produced with more than one intonation phrase; in this case, the single intonation phrase marks only a fragment of a TCU. TCUs thus require three kinds of completion: syntactic, intonational, and pragmatic. Within their context of occurrence, they form a possibly complete syntactic structure, a possibly complete intonational structure, and at the same time a possibly complete pragmatic action (Ford and Thompson, 1996).

Once produced, TCUs can still be extended – grammatically, intonationally, and pragmatically – should circumstances require it (e.g., if no response from an interlocutor is forthcoming; Ford *et al.*, 2002). This phenomenon has been called 'incrementing' (Schegloff, 1996, 2001). Increments are bits of speech tacked on the end of a prior TCU that are

grammatically dependent on it. They in essence re-complete the prior unit and provide another occasion for possible turn transition. Often, increments are also prosodically dependent on the prior unit: They re-do or reshape its phonetic contour, they are fitted to it in terms of pitch range and placement, and they have loudness, tempo, and articulatory characteristics analogous to it. The prosodic shape of increments thus cues their syntagmatic relationship to the TCU that they are continuing (Walker, 2004).

The Turn

Turns-at-talk may consist of one or more than one TCU. In the latter case, they may be planned as such from the outset or they may become multiunit over time (e.g., when interlocutors decline to take over the floor and the current speaker continues to talk; Schegloff, 1982). Whether a turn is transition-ready or not – that is, whether or not the talk has reached a transition-relevance place (TRP), a place in talk where the floor may legitimately shift to another speaker – is often cued prosodically. Research has shown, however, that the prosody of turn delimitation is specific to the variety of English being spoken (Local *et al.*, 1985, 1986; Wells and Peppé, 1996). Whereas, for instance, both Tyneside and Ulster varieties appear to deploy rallentando and decrescendo over the last foot or two of a unit, with a swell of loudness and lengthening on the final accented (and lexically stressed) syllable, in London Jamaican there is no rallentando or descrescendo and only the very last (often lexically unstressed) syllable of the unit has a narrow fall with creaky voice. For English varieties with so-called stress timing, it appears to be the shape of the accent that projects an upcoming TRP. In the West Midlands, for instance, one type of TRP-projecting accent regularly falls on a syllable with centering vowel quality and is lower, louder, and longer than surrounding syllables; accents that lack these features do not appear to project that the turn is about to end (Wells and Macfarlane, 1998).

Some multiunit turns arise because speakers suppress possible floor transition at the end of a TCU and rush into the next one ('rush through'; Schegloff, 1982, 1996). In these cases, prosodic features cue what the speaker is doing. The end of the first unit tends to lack the rallentando and final lengthening associated with prosodic completion. The first syllables of the new unit are likely to come earlier than expected based on the speaker's rate of speech so far. There is also often a sudden break in pitch and volume levels between the end of the first unit and the beginning of the next. Yet in a kind of phonetic sandhi, selected articulatory features from the first unit may encroach onto the new one (Local and Walker, 2004).

The Sequence

Sequences arise through the pursuit of courses of action in talk-in-interaction. A sequence consists minimally of a single adjacency pair – an initiatory turn and a corresponding response turn – such as greeting–return of greeting, question–answer, and assessment–second assessment. Sequences can, however, be expanded through presequences, insert sequences, and postsequences (Schegloff, 1995). Although sequences are structured through action, there are various prosodic cues to their emerging structure. In standard English, for instance, second pair-parts are normatively integrated with first pair-parts rhythmically. This means that the timing of the first accented syllable of the second pair-part is expected to be synchronized with the timing of the accented syllables at the end of the first pair-part. In other words, the regular delivery of the final accented syllables at the end of a first turn establishes a metric according to which the onset of the second turn is timed (Couper-Kuhlen, 1991, 1993). Departures from the local rhythmic metric (e.g., a next speaker coming in too early or too late with respect to the beat established in prior talk) cue various sorts of contextually interpretable problems in talk (Auer *et al.*, 1999). An ongoing rhythmic beat established in a first turn and continued and/or modified in subsequent turns is thus a hallmark of a coherent sequence in talk: series of turns engaged in a single course of action 'hang together' rhythmically in time.

Series of turns within a sequence are also fitted to one another in terms of pitch and loudness. Second pair-parts are, as a rule, never louder than first pair-parts (Goldberg, 1978). Their overall pitch range, typically reflected in the height of the first accented syllable, tends to be no higher than that of the corresponding first pair-part. That is, in terms of both pitch and loudness, series of turns within a sequence create an overriding declination line (supradeclination), with first turns in a larger sequence typically beginning high and loud and subsequent turns gradually lowering the pitch and volume settings (Schuetze-Coburn *et al.*, 1991). This type of declination is all the more remarkable in that it is jointly constructed and coordinated across speakers. Turns that begin a new sequence are cued as such by having high pitch from the outset (i.e., on both the first accented and any preceding unaccented syllables) (Couper-Kuhlen, 2001, 2003). Turns that extend a sequence under way begin in a fashion that reflects their continuing status. Their initial pitch and volume levels are fitted to those

of prior talk: these turns are thus cued as continuing on from something already begun rather than beginning something new (Couper-Kuhlen, 2004).

Conclusion

One of the advantages of prosodic cues to units in both scripted and unscripted spoken discourse is that they are produced and processed as speech or talk emerges. Of course, information concerning the structure of discourse can be conveyed in so many words (i.e., metalinguistically): "I'm beginning a new sentence" or "This is a new paragraph." However, it is most efficiently conveyed when produced simultaneously with the speech to which it refers. The cueing of structural units prosodically has numerous value-added effects. In discourse that is scripted and read aloud primarily for aesthetic or entertainment purposes (e.g., poetry reading and talking books), it allows for a layer of interpretative meaning above and beyond that suggested through lines, stanzas, and/or sentences and paragraphs. In unscripted interactive discourse, cueing with nonverbal means provides for a measure of indeterminacy, which in turn facilitates *in situ* negotiation.

Prosodic Morphology

J J McCarthy, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

The phrase 'prosodic morphology' (hereafter, PM) refers to a theory and to a class of phenomena to which that theory is applied. The theory of PM deals broadly with the relationship between phonological and morphological structure, particularly restrictions on the size and shape of words, stems, and morphemes. This article presents an overview of the theory of PM and its applications.

The Theory of Prosodic Morphology

PM is a theory of how morphological and phonological determinants of linguistic form interact. The theory focuses on understanding how prosodic structure impinges on certain kinds of morphology, such as reduplication and infixation. In McCarthy and Prince (1986/1996, 1990a), three essential claims are advanced about PM:

(1) Principles of PM
  a. Prosodic morphology hypothesis
     Templates are defined in terms of the authentic units of prosody: mora (μ), syllable (σ), foot (Ft), phonological word (PWd).
  b. Template satisfaction condition
     Satisfaction of templatic constraints is obligatory and is determined by the principles of prosody, both universal and language-specific.
  c. Prosodic circumscription
     The domain to which morphological operations apply may be circumscribed by prosodic criteria as well as by the more familiar morphological ones.

A template is a restriction on the size and shape of an affix, stem, or word. According to the prosodic morphology hypothesis (1a), all such restrictions must be stated in prosodic terms. Since templates are defined prosodically, satisfaction of templates (1b) is determined by the same principles that govern prosodic structure generally, such as foot binarity (see (4) below). Circumscription (1c) is a mechanism for delimiting a prosodically defined portion of a word to which a morphological process is then applied; it is important in the analysis of infixation and other phenomena. In short, templates and circumscription must be stated in terms of the vocabulary of prosody and must respect the well-formedness requirements of prosody.

These principles are intended to address a fundamental explanatory goal: to reduce or eliminate the descriptive apparatus that is specific to particular empirical domains such as reduplication and instead derive the properties of those domains from general and independently motivated principles. Claims (1a, b, c) assert that prosodic theory is where these independent principles are to be found. Indeed, the goal of independent explanation is more important than the principles, and subsequent work has pursued the same explanatory goal while departing from these principles in certain respects. Some of this later work is reviewed below.

On the morphological side, the theory of PM incorporates few assumptions. The morphological constituents root, stem, and affix form a labeled bracketing, essentially along the lines of Selkirk's (1982) word-syntax. Most work in PM adopts a view of morphology that is morpheme-based, under the broad rubric of item-and-arrangement models, though the implementation of prosodic circumscription in McCarthy and Prince (1990a) is process-based.

On the phonological side, prosodic morphology presupposes the prosodic hierarchy in (2) (cf. Selkirk, 1980).

Prosodic Morphology

J J McCarthy, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

The phrase 'prosodic morphology' (hereafter, PM) refers to a theory and to a class of phenomena to which that theory is applied. The theory of PM deals broadly with the relationship between phonological and morphological structure, particularly restrictions on the size and shape of words, stems, and morphemes. This article presents an overview of the theory of PM and its applications.

The Theory of Prosodic Morphology

PM is a theory of how morphological and phonological determinants of linguistic form interact. The theory focuses on understanding how prosodic structure impinges on certain kinds of morphology, such as reduplication and infixation. In McCarthy and Prince (1986/1996, 1990a), three essential claims are advanced about PM:

(1) Principles of PM
  a. Prosodic morphology hypothesis
     Templates are defined in terms of the authentic units of prosody: mora (μ), syllable (σ), foot (Ft), phonological word (PWd).
  b. Template satisfaction condition
     Satisfaction of templatic constraints is obligatory and is determined by the principles of prosody, both universal and language-specific.
  c. Prosodic circumscription
     The domain to which morphological operations apply may be circumscribed by prosodic criteria as well as by the more familiar morphological ones.

A template is a restriction on the size and shape of an affix, stem, or word. According to the prosodic morphology hypothesis (1a), all such restrictions must be stated in prosodic terms. Since templates are defined prosodically, satisfaction of templates (1b) is determined by the same principles that govern prosodic structure generally, such as foot binarity (see (4) below). Circumscription (1c) is a mechanism for delimiting a prosodically defined portion of a word to which a morphological process is then applied; it is important in the analysis of infixation and other phenomena. In short, templates and circumscription must be stated in terms of the vocabulary of prosody and must respect the well-formedness requirements of prosody.

These principles are intended to address a fundamental explanatory goal: to reduce or eliminate the descriptive apparatus that is specific to particular empirical domains such as reduplication and instead derive the properties of those domains from general and independently motivated principles. Claims (1a, b, c) assert that prosodic theory is where these independent principles are to be found. Indeed, the goal of independent explanation is more important than the principles, and subsequent work has pursued the same explanatory goal while departing from these principles in certain respects. Some of this later work is reviewed below.

On the morphological side, the theory of PM incorporates few assumptions. The morphological constituents root, stem, and affix form a labeled bracketing, essentially along the lines of Selkirk's (1982) word-syntax. Most work in PM adopts a view of morphology that is morpheme-based, under the broad rubric of item-and-arrangement models, though the implementation of prosodic circumscription in McCarthy and Prince (1990a) is process-based.

On the phonological side, prosodic morphology presupposes the prosodic hierarchy in (2) (cf. Selkirk, 1980).

(2) Prosodic hierarchy

Phonological word	PWd
Foot	Ft
Syllable	σ
Mora	μ

The mora is the basic unit of syllable weight; in the most common syllable-weight typology, short open syllables such as *pa* are monomoraic, and long-voweled or closed syllables like *pa:* or *pat* are bimoraic.

The metrical foot typology assumed in PM is based on Hayes (1987, 1995) and McCarthy and Prince (1986/1996). The typology, given in (3), uses the notations L for a monomoraic (or light) syllable, H for a bimoraic (or heavy) syllable, and σ for a syllable of unspecified weight.

(3)	Iambic foot	Trochaic foot	Syllabic foot
	LH	H, LL	$\sigma\sigma$
	LL, H		

The basic foot typology does not include degenerate feet, those consisting of a single light syllable (if the foot is iambic or trochaic) or a single syllable (if the foot is syllabic). The general condition on foot form in (4) expresses the markedness of degenerate feet.

(4) Foot Binarity
Feet are binary under syllabic or moraic analysis.

The advent of Optimality Theory (Prince and Smolensky, 2004) has had a significant influence on the development of the theory of PM. In Optimality Theory, constraints on linguistic forms are ranked and violable. Constraint violability turns out to be an extremely useful concept in PM, as some of the analyses below will show.

Word and Stem Shape Restrictions

The prosodic hierarchy and foot binarity, taken together, derive the key notion of a minimal word (Broselow, 1982; McCarthy and Prince, 1986/1996; Prince, 1980). According to the prosodic hierarchy, any instance of the category phonological word must contain at least one foot. By foot binarity, every foot must be bimoraic or disyllabic. By transitivity, then, a phonological word must contain at least two moras or two syllables.

The grammatical significance of word minimality is determined by constraints on the interface between morphological and prosodic structure. In nearly all languages, every lexical or content word – that is, every member of the open classes noun, verb, and adjective – corresponds to a phonological word. Therefore, if phonological words are minimally binary, lexical words will be observed to have a minimum phonological size. In some languages, not only lexical words, but also the stems embedded in them must correspond to phonological words and may be subject to binarity requirements as well.

Both of these minimality effects can be illustrated with data from Axininca Campa (Ashéninca Pichis) (Arawakan, Peru). In this language, word-final vowels are shortened (5a), but not in monosyllables (5b) (Payne, 1981; Spring, 1990).

(5) a.	/sampa:/	sampa	'balsa'	cf. no-sampa:-ti 'my balsa'
	/sawo:/	sawo	'case'	cf. no-sawo:-ti 'my case'
vs.	/sima/	sima	'fish'	cf. no-sima-ni 'my fish'
b.	/mi:/	mi:	'otter'	cf. no-mi:-ni 'my otter'
	/so:/	so:	'sloth'	cf. no-so:-ni 'my sloth'

Final vowel shortening is blocked in monosyllables by the joint effects of the three constraints mentioned: every lexical word corresponds to a phonological word, so 'otter' has the phonological structure $[mi:]_{PWd}$; every phonological word contains a foot as its head, so 'otter' has the foot structure $[(mi:)_{Ft}]_{PWd}$; and feet are binary, so $*[(mi)_{Ft}]_{PWd}$ is ruled out.

Axininca Campa also shows word-minimality effects at the level of the stem. Before certain suffixes, monomoraic roots are augmented by adding the syllable *ta*, thereby making them bimoraic, as shown in (6).

(6)	Root	Morphological structure Prosodic structure
	/na/	$\{\{\{na\}_{St}$ piro$\}_{St}$ a:nts^{h}i$\}_{St}$ $[[(nata)_{Ft}]_{PWd}$ pirota:nts^{h}i$]_{PWd}$
	/t^{h}o/	$\{\{\{\{\{t^ho\}_{St}$ RED$\}_{St}$ wai$\}_{St}$ ak$\}_{St}$ i$\}_{St}$ $[[(t^hota)_{Ft}]_{PWd}$ t^hotawaitaki$]_{PWd}$

(Glosses: 'to carry well', 'has continued to kiss more and more')

Under standard assumptions about word syntax, affixed forms are bracketed into recursive stem structure, and the most deeply embedded stem is the root. Before suffixes such as *-piro* or reduplicative -RED, that innermost stem must correspond to a phonological word. For reasons already given, phonological words are minimally bimoraic. Monomoraic roots such as /na/ or /t^{h}o/ are not big enough to support a properly footed phonological word, so epenthetic *ta* must be added. Taken together with the observations about the lack of vowel shortening in monosyllables, this shows that word minimality can both block and trigger phonological processes.

Axininca Campa also illustrates how Optimality Theory can contribute to the understanding of PM. The suffixes that induce augmentation of a preceding

monomoraic root are exactly those that begin with consonants. Suffixes that begin with vowels in underlying representation do not trigger augmentation: /{tʰo}$_{St}$ aːntsʰi/→ *tʰotaːntsʰi*, **tʰota.aːntsʰi*, **tʰotataːntsʰi* 'to kiss'. The reason for this difference lies in constraint interaction. In Optimality-Theoretic terms, the relationship between stems and phonological words is expressed by a ranked, violable constraint on the prosody–morphology interface. This constraint can be called ALIGN-STEM (for details, see McCarthy and Prince, 1993a). ALIGN-STEM is satisfied by [(*nata*)$_{Ft}$]$_{PWd}$ *piro* because the suffix *-piro* is immediately preceded by the right edge of a phonological word. But ALIGN-STEM is violated by *tʰotaːntsʰi* because the alternatives, [(*tʰota*)$_{Ft}$]$_{PWd}$ *aːntsʰi* and *[(*tʰotat*)$_{Ft}$]$_{PWd}$ *aːntsʰi*, violate the constraint ONSET, which prohibits the vowel-initial syllable *aːn*. The interaction of ONSET and ALIGN-STEM through ranking is shown in (7).

(7) ONSET >> ALIGN-STEM

/{tʰo}$_{St}$ aːntsʰi/	ONSET	ALIGN-STEM
a. ☞ tʰotaːntsʰi		*
b. [(tʰota)$_{Ft}$]$_{PWd}$ aːntsʰi	*!	
c. [(tʰotat)$_{Ft}$]$_{PWd}$ aːntsʰi	*!	

To sum up, augmentation in Axininca Campa is a response to word-minimality requirements that derive from the prosodic hierarchy and foot binarity. Presuffixal augmentation further calls on a constraint on the morphology–prosody interface, ALIGN-STEM, that imposes phonological-word status on the stems to which suffixes are attached. Constraint interaction through ranking is crucial in explaining why consonant-initial suffixes induce augmentation and vowel-initial suffixes do not. The consonant-initial/vowel-initial dichotomy is purely descriptive; the real difference is between suffixes like *-piro* that can satisfy both ONSET and ALIGN-STEM versus suffixes such as *-aːntsʰi* that can satisfy one or the other of these constraints, but not both. As these constraints are ranked in (7), ONSET prevails: vowel-initial suffixes are not preceded by stems that are also phonological words, and so there is no need for augmentation.

Templatic Morphology

In some languages, restrictions on the size and shape of words or stems are used to mark morphological distinctions. This phenomenon is called templatic, template-mapping, or root-and-pattern morphology.

The best attested type of templatic morphology is subtractive: nicknames and the like are formed in many languages by mapping the full name onto a minimal-word template. Descriptively, all of the segments of the original name are discarded, leaving only enough to make a single metrical foot, the minimal phonological word. Some examples appear in (8).

(8) a. Central Alaskan Yupik Eskimo (Central Yupik) (A. Woodbury, personal communication)

Name	Proximal Vocative
aŋukaʁnaq	aŋ ∼ aŋuk
nupiʁak	nup ∼ nupix/nupik
aŋivʁan	aŋif

b. Japanese (Poser, 1990)

Name	Hypocoristic
ti	tiː-ʧan
ʃuːsuke	ʃuː-ʧan
taizoo	tai-ʧan
kinsuke	kin-ʧan
midori	miː-ʧan ∼ mit-ʧan ∼ mido-ʧan

c. English

Name	Nickname
Mortimer	Mort, Mortie
Cynthia	Cynth, Cindy
Marjorie	Marge, Margie
Angela	Ange [æñʤ], Angie,
Edward	Ed, Eddie, *but* *Edwie
Abraham	Abe, Abie, *but* *Abrie
Jacqueline	Jackie, *but* *Jacquie (=[ʤækwiː])

The stress system of Yup'ik (8a) is based on the iambic foot, and the truncated names exactly match the expansions of the iambic foot that are consistent with foot binarity (see [3]). The template in Yup'ik, as in the other two languages, is the minimal word (MinWd). Though Japanese (8b) does not have a stress system, there is abundant evidence from various quarters in support of trochaic feet (Ito, 1990; Poser, 1990), and the hypocoristic nicknames consist of a single heavy syllable or two light syllables, which are the licit expansions of the trochee. English (8c) also has trochaic feet, and English nicknames typically contain a single heavy syllable, to which the diminutive suffix *-ie* may be added. In accordance with the template satisfaction condition (1b), the mapping of a name to the minimal-word template respects independently motivated restrictions on prosodic structure in English. That is why **Edwie* and **Abrie* are ill formed: the suffix *-ie* is external to the MinWd template, and **Edw* or **Abr* are not possible monosyllables.

Though nickname formation is rather limited in scope, root-and-pattern morphology is an utterly pervasive feature of some morphological systems, particularly in the Afro-Asiatic family, but also in various Penutian languages such as Miwok (Southern

Sierra Miwok), Yokuts, and Takelma. These systems are all rather complex and difficult to summarize briefly, but it is possible to get a general feel for the mode of analysis by a brief glance at one of them.

The shapes of canonical noun stems in Arabic illustrate some basic principles (McCarthy and Prince, 1990b). (A noun stem is canonical if it has a broken plural, a concept to be explained below.) The permitted noun stems are summarized in (9), classified according to syllabic structure with an example of each type.

(9) a. H b. LL c. LH d. HL f. HH
bahr badal wazi:r ka:tib, ʤa:mu:s,
xanʤar ʤumhu:r
'sea', 'substitute', 'vizier', 'writer', 'buffalo', 'dagger', 'multitude'

All patterns are well represented in the Arabic lexicon, with hundreds of examples of each.

The classification of nouns in (9) according to the syllable-weight patterns assumes final consonant extrametricality, which is independently motivated in Arabic. With the extrametrical consonant set aside, the shapes of these noun stems range from a lower bound at the bimoraic minimal word (H or LL) to an upper bound at the maximal disyllable HH. These observations can be expressed in terms of prosodic conditions on noun stems:

(10) a. Minimally bimoraic b. Maximally disyllabic
$\text{Stem}_N = \text{PWd}$ $\text{Stem}_N \leq \sigma\sigma$

Because the morphological category Stem_N is equated with the phonological word, a Stem_N must contain a foot, under the prosodic hierarchy (2), and so it is minimally bimoraic, as required by foot binarity (4). The maximality condition is a natural one under general considerations of locality, which impose an upper limit of two on rules that count (McCarthy and Prince, 1986/1996). The minimality and maximality conditions define a family of templates in Arabic, with each member of that family available for particular morphological functions in the nominal system. This shows that the fundamental structural properties of root-and-pattern morphological systems can and should be characterized in prosodic terms.

Reduplication

In reduplicative morphology, a copy of a root or stem is mapped to a template. According to (1a, b), the reduplicative template must be defined and satisfied in accordance with prosodic principles.

A cursory survey of reduplicative templates across languages finds only a limited array of options. Total reduplication (11a) copies the entire root or stem, regardless of its size. Of the types of partial reduplication, the largest is disyllabic (11b), with a template consisting of a single foot or a minimal word. Monosyllabic templates can be heavy (11c) or light (11d); the smallest monosyllabic template is the core syllable, which consists of a single onset consonant and a vowel (11e).

(11) a. Indonesian total reduplication

rumah	rumah-rumah	'house/pl.'
ibu	ibu-ibu	'mother/pl.'
lalat	lalat-lalat	'fly/pl.'
harian	harian-harian	'newspaper/pl.'

b. Diyari (Dieri) minimal word reduplication (Austin, 1981)

ŋama	ŋama-ŋama	'to sit'
kanku	kanku-kanku	'boy'
kuɭkuŋa	kuɭku-kuɭkuŋa	'to jump'
tʲilparku	tʲilpa-tʲilparku	'bird species'

c. Ilokano (Ilocano) heavy syllable reduplication (Hayes and Abad, 1989)

kaldíŋ	kal-kaldíŋ	'goat/pl.'
púsa	pus-púsa	'cat/pl.'
ʤjánitor	ʤjan-ʤjánitor	'janitor/pl.'
kristʃjáno	kris-kristjáno	'Christian/pl.'
trabáho	ʔag-trab-trabáho	'to work/is working'

d. Ilokano light syllable reduplication (Hayes and Abad, 1989)

bunéŋ	si-bu-bunéŋ	'buneng/carrying a buneng'
ʤjáket	si-ʤja-ʤjáket	'jacket/wearing a jacket'
pandilíŋ	si-pa-pandilíŋ	'skirt/wearing a skirt'
dʒjánitor	ʔagin-dʒja-dʒjánitor	'janitor/pretend to be a janitor'
trabáho	ʔagin-tra-trabáho	'to work/pretend to work'

e. Sanskrit core syllable reduplication (Steriade, 1988)

pat	pa-pát-a	'fly/perf.'
prat^h	pa-prát^h-a	'spread/perf.'
mna:	ma-mná:-u	'note/perf.'
stamb^h	ta-stamb^h-a	'prop/perf.'

The template for total reduplication (11a) is the unmodified phonological word, PWd. This template is as flexible in size as words themselves are, so it elicits complete and exact copying of the word to which it is attached. The foot or minimal word, MinWd, whose role as nickname template has already been discussed, also shows up as a rather common reduplicative template (11b). The various monosyllabic templates (11c–e) are differentiated by syllable weight and onset complexity. Sanskrit (11e)

permits complex onsets in roots but not in the reduplicative affix; the consonant that is reduplicated is the less sonorous member of the cluster (*p* is less sonorous than *r* and *t* than *s*), or else the first when they are equal sonority.

The role and status of the template satisfaction condition (1b) in reduplication can perhaps best be appreciated by applying recent developments in Optimality Theory (McCarthy and Prince, 1993b, 1994, 1995a, 1999). Reduplication is a matter of reconciling the often competing demands of markedness constraints and MAX-BR. (MAX-BR requires *max*imal copying of the *b*ase's segments by the *r*eduplicative morpheme.) MAX-BR always militates in favor of copying more, whereas prosodic markedness often favors copying less. The ranking of these markedness constraints relative to MAX-BR is therefore crucial in determining the extent of reduplicative copying (*see also* **Morphology: Optimality Theory**).

Sanskrit will serve to illustrate this mode of analysis. Basic language typology shows that onset clusters are marked c – for example, although some languages permit onset clusters, no language literally requires them, and some languages prohibit them outright. There is, then, ample foundation for positing the syllable markedness constraint *COMPLEX-ONSET. In languages without onset clusters, *COMPLEX-ONSET must dominate some input-output faithfulness constraint, such as MAX-IO, which prohibits deletion. (MAX-IO requires *max*imal preservation of the *i*nput's segments by the *o*utput.) Sanskrit, however, allows onset clusters, so the ranking of these two constraints is the other way around. But Sanskrit bans onset clusters from the reduplicative affix, even at the expense of less than perfect copying. Example (12) provides an explanation for this difference:

(12) MAX-IO >> *COMPLEX-ONSET >> MAX-BR

/RED+druv/	MAX-IO	*COMPLEX-ONSET	MAX-BR
a. ☞ du-druv		*	**
b. dru-druv		**!	*
c. du-duv	*!		*

With this ranking, *COMPLEX-ONSET limits the reduplicative affix to unmarked structure at the expense of less complete copying. But where faithfulness to the input rather than completeness of copying is at stake, MAX-IO prevails. This allows the language as a whole, outside the reduplicative affix, to have complex onsets.

Axininca Campa supplies another example. Suffixing reduplication makes a complete copy of a consonant-initial root (13a), but it skips over the first syllable of a vowel-initial root (13b).

(13) a. kawosi-kawosi 'bathe'
t^{h}aːŋki-t^{h}aːŋki 'hurry'
kint^{h}a-kint^{h}a 'tell'
b. osaŋkina-saŋkina 'write'
osampi-sampi 'ask'

Total copying of vowel-initial roots would produce a vowel-initial syllable, which is a violation of ONSET. Since this outcome is avoided, ONSET must dominate MAX-BR in Axininca Campa (see [14]).

(14) ONSET >> MAX-BR

/osaŋkina + RED/	ONSET	MAX-BR
a. ☞ osaŋkina-saŋkina		*
b. osaŋkina-osaŋkina	*!	

This example is of particular interest because it shows that the basic typology of reduplication in (11) is incomplete. Even total reduplication can be limited by the force of markedness constraints.

The broader theme emerging from examples such as Sanskrit and Axininca Campa is that template satisfaction can be affected by any markedness constraint if it is ranked appropriately. The bolder and therefore more interesting hypothesis is that the 'template' is a purely derivative notion: it is a description of a reduplicative pattern that emerges from constraint rankings like those in (12) and (14). In other words, templates are not primitives of morphological and phonological description, as they were in the original conception of PM theory. Rather, the work of templates is done by markedness constraints such as *COMPLEX-ONSET and ONSET, all of which are independently motivated on language typology. Through ranking, these constraints can affect reduplicative or other templatic structures in a language without affecting the language as a whole. The hypothesis just sketched and the research program in support of it are known as Generalized Template Theory (McCarthy and Prince, 1994, 1995a, 1995b, 1999).

Prosodic Circumscription

There is one remaining aspect of PM theory to discuss: prosodic circumscription. The base to which a morphological operation is applied is usually a grammatical category such as root, stem, or (morphosyntactic) word. The result is ordinary prefixation or suffixation. Under prosodic circumscription, though, a morphological operation is applied to a base that is a prosodically delimited substring within the

grammatical category. The result is often some sort of infix, though there are many applications of prosodic circumscription extending beyond infixation. The explanation and examples below are drawn from McCarthy and Prince (1990a, 1995b).

Ulwa (Sumo Tawahka) (Misumalpan, Nicaragua) presents a remarkably clear case of infixation by prosodic circumscription. The possessive in Ulwa is marked by a set of infixes located after the stressed syllable of the noun, as shown in (15a, b) (Hale and Lacayo Blanco, 1989).

(15) a. Possessive paradigm

sú:lu	'dog'
sú:kilu	'my dog'
sú:malu	'thy dog'
sú:kalu	'his/her dog'
sú:kinalu	'our (excl.) dog'
sú:nilu	'our (incl.) dog'
sú:manalu	'your dog'
sú:kanalu	'their dog'

b. Further examples

bás-ka	'his hair'
kí:-ka	'his stone'
ás-ka-na	'his clothes'
saná-ka	'his deer'
amák-ka	'his bee'
sapá:-ka	'his forehead'
siwá-ka-nak	'his root'
aná:-ka-la:ka	'his chin'
arák-ka-bus	'his gun'

Ulwa has iambic feet assigned from left to right. An iambic foot consists of a single heavy syllable or a sequence of two syllables, the first of which is light (3). Therefore, stress falls on the first syllable if it is heavy (*sú:lu*, *ásna*), otherwise on the second syllable. The location of the possessive morphemes, then, is immediately after the first or main-stressed foot of the word.

The fundamental idea in prosodic circumscription theory is that the Ulwa possessive morphemes are actually suffixes, but suffixes on the prosodically circumscribed initial foot within the Ulwa noun stem. The central element of prosodic circumscription theory is a parsing function Φ(C, E, B), which returns the prosodic constituent C that sits at the edge E of the base B. The function Φ factors B into two parts: the kernel B:Φ is the part that satisfies the constraint (C, E), and the residue B/Φ is the rest of B. With '*' standing for the relation between the two factors (normally left- or right-concatenation), the identity in (16) holds.

(16) Factoring of B by Φ
B = B:Φ * B/Φ

There are two main types of prosodic circumscription, positive and negative. In positive circumscription, the B:Φ factor serves as the input to a morphological operation. Call that operation O(X). Then O:Φ – the same operation, but conditioned by positive circumscription of (C, E) – is defined as in (17).

(17) Positive prosodic circumscription
O:Φ(B) = O(B:Φ) * B/Φ

That is, to apply O to B under positive prosodic circumscription is to apply O to B:Φ, concatenating the result with B/Φ in the same way that the kernel B:Φ concatenates with the residue B/Φ in the base B. In this way, the operation O:Φ inherits everything that linguistic theory says about O, except its domain of application.

In Ulwa, the factor returned by Φ is a foot at the left edge, so the Ulwa possessive is characterized as O:Φ(Ft, Left), where O is a morphological operation that can be called 'Suffix POSS.' For example, the factoring of *karásmak* 'knee' is shown in (18).

(18) O:Φ(karásmak) = O(karásmak:Φ) * karásmak/Φ
= O(karás) * mak
= karás-ka * mak
= karáskamak

The initial iambic foot *karás*, rather than the whole noun, functions as the base for suffixation of the possessive morpheme. With words consisting of a single iambic foot, such as *bas* or *ki:*, the infixes are authentic suffixes because B and B:Φ are coextensive.

The Arabic broken plural and diminutive present another example of positive prosodic circumscription. In Arabic, the productive plural formation and the diminutive are expressed by imposing a LH iambic foot on the singular noun stem. Singular nouns come in diverse shapes, but this iambic template affects only a portion of the noun. The affected portion of the singular is italicized in the first column of (19), as is the iambic portion of the plural and diminutive in the second and third columns.

(19)

Singular	plural	diminutive	
*ħuk*m	/*ħaka:*m/	*ħukaj*m	'judgment'
*ʕina*b	/*ʕana:*b/	*ʕunaj*b	'grape'
dʒazi:r-at	/*dʒaza:*wir/	/*dʒuzaj*wir/	'island'
*ʃa:γ*il	*ʃawa:γ*il	*ʃuwajγ*il	'engrossing'
dʒa:mu:s	*dʒawa:*mi:s	*dʒuwaj*mi:s	'buffalo'
*dʒun*dub	*dʒana:*dib	*dʒunaj*dib	'locust'
*sul*tˤa:n	*sala:*tˤi:n	*sulaj*tˤi:n	'sultan'

Underlying representations are written in virgules for those forms undergoing additional phonological processes that obscure some of the effects of the morphology.

Plural and diminutive morphology have characteristic effects on word shape, vowel quality, and appearance of the glides *w* and *j*. Prosodic circumscription is responsible for the word shape, which is therefore the

focus of attention here. Descriptively, plurals and diminutives have both invariant and varying properties of word shape. The invariant is the initial LH sequence, which has been italicized in (19). The varying portion of the plural and diminutive ranges from a single consonant (e.g., the final *m* of *ħukajm*) to a heavy syllable plus a consonant (e.g., the final *miːs* of *dʒuwajmiːs*). The shape of the varying portion is determined by the corresponding singular stem: it matches the unitalicized portion of the singular (e.g., the *m* of *ħukajm* matches the *m* of *ħukm* and the *miːs* of *dʒuwajmiːs* matches the *muːs* of *dʒaːmuːs*).

This division into invariant and varying portions is a consequence of prosodic circumscription. The italicized portion of the singular is the positively circumscribed domain, a trochaic foot, which is also the minimal word of Arabic. This string, the kernel of prosodic circumscription, is mapped onto a LH iambic template, which realizes the plural and diminutive morphology. The residue of circumscription, which varies in size depending on the singular, is simply attached unchanged to the templatic portion. Thus, the morphological operation O is mapping to an iambic template, and the circumscriptional function is Φ(MinWd, Left).

In positive prosodic circumscription, as we have seen, the kernel of the Φ-parse is submitted to the morphological operation O. Negative prosodic circumscription is fully symmetrical: the residue of the parse is submitted to the morphological operation. The negatively circumscribed operation O/Φ(B) – the application of O to the base B minus some edge constituent – is defined in (20).

(20) Negative prosodic circumscription
$$O/\Phi(B) = B{:}\Phi * O(B/\Phi)$$

Except that it is defined in operational terms, this is essentially equivalent to representational extrametricality in metrical phonology. To apply O to B under extrametricality is simply to apply O to B/Φ, concatenating the result with B:Φ in the same way that the residue B/Φ concatenates with the kernel B:Φ in the original base B.

A common type of infixing reduplication requires negative circumscription of an initial onsetless syllable, one that starts with a vowel rather than a consonant. An example of this comes from Timugon Murut (Austronesian, Malaysia), as shown in (21) (Prentice, 1971).

(21)	bulud	bu-bulud	'hill/ridge'
	limo	li-limo	'five/about five'
	abalan	a-ba-balan	'bathes/often bathes'
	ompodon	om-po-podon	'flatter/always flatter'

The reduplicative template in Timugon Murut is a light syllable. It copies material of the base, minus an initial onsetless syllable, if any. It can therefore be characterized as O/Φ(σ_V, Left), where σ_V is a temporary expedient for referring to onsetless syllables and O stands for the operation of prefixing the reduplicative morpheme. Applied to the final example in (21), this schema yields the result in (22).

(22)
$$\begin{aligned} O/\Phi(\text{ompodon}) &= \text{ompodon}{:}\Phi * O(\text{ompodon}/\Phi) \\ &= \text{om} * O(\text{podon}) \\ &= \text{om} * \sigma_\mu\text{-podon} \\ &= \text{om} * \text{po-podon} \\ &= \text{ompopodon} \end{aligned}$$

The morphological base *ompodon*, minus its initial syllable *om*, functions as the prosodically circumscribed base to which the operation of prefixing a σ_μ template applies. Crucially, it is the residue of circumscription, rather than the kernel, that is the target of the morphological operation. When the initial syllable has an onset, as in *bulud*, the kernel of circumscription is empty, and the entire base *bulud* is the residue to which the reduplicative template is prefixed.

Prosodic circumscription unifies a range of phenomena that are sensitive to phonological subdomains, including operations that target a constituent, as in Ulwa, and those that exclude a constituent, as in Timugon Murut. The theory of PM situates circumscription within broader principles of phonology and morphology, thereby contributing to the explanatory goals of the enterprise. But Timugon Murut also discloses some limits of prosodic circumscription theory. One problem is that the onsetless syllable is not a legitimate prosodic constituent – on the contrary, it is a *defective* prosodic constituent. So its role in Timugon Murut circumscription is inconsistent with principle (1c), which says that only recognized constituents can be employed in circumscription. A more serious problem is that infixes with the same locus of placement as Timugon Murut's are always reduplicative in known cases. Reduplicative infixes that go after an initial onsetless syllable but are otherwise prefixed are not uncommon, yet ordinary, non-reduplicative infixes never have exactly this distribution. Cross-linguistically, then, there is an interactional effect: positioning an affix after an initial onsetless syllable is dependent upon the affix's being templatic and reduplicative rather than segmentally specified. Circumscription theory cannot explain this, because it formally divorces the placement of an affix (which is determined by the arguments of Φ) from the structural nature of the affix (which is determined by the operation O). Research on PM within Optimality Theory has sought to address these and other problems (*see* **Morphology: Optimality Theory**).

Positive and negative circumscription are essentially symmetrical mechanisms for defining the base of a morphological operation within a larger word. More loosely connected to the theory of circumscription is the theory of prosodic delimitation, which applies in situations where minimal and supraminimal bases are subject to different morphological operations. For example, in Dyirbal (Pama-Nyungan, Australia) (23), disyllabic and longer bases take different allomorphs of the ergative suffix (Dixon, 1972), while in Axininca Campa (24), bimoraic and longer bases take different allomorphs of the 'possessed' suffix:

(23)

Noun stem	Noun+ergative	
yaʈa	yaʈa-ŋgu	'man'
yamani	yamani-gu	'rainbow'
balagara	balagara-gu	'they'

(24)

mi:	no-mi:-ni
sima	no-sima-ni
ʦʰimi:	no-ʦʰimi:-ti
mana:nawo	no-mana:nawo-ti
mi:	no-mi:-ni
'otter/my otter'	no-mi:-ni
sima	no-sima-ni
'fish/my fish'	

In Dyirbal, the generalization is that the ergative suffix takes the allomorph *-ŋgu* with disyllabic bases (=MinWd), and the allomorph *-gu* with longer bases. In Axininca Campa, the possessed suffix is *-ni* with minimal, bimoraic bases and *-ti* with longer ones. A minimality criterion partitions the lexicon into two sets, and suffixal allomorphy is determined by this partitioning. The suffix alternations in both languages are truly allomorphic, since they do not reflect any systematic phonological pattern.

Prosodic delimitation, like positive prosodic circumscription in Arabic, calls on Φ(MinWd), but it puts the result to different use. Specifically, prosodic delimitation partitions the lexicon into those bases where B:Φ, the Φ-circumscribed kernel of B, is identical to B, and those where B:Φ is less than B. This special sense of Φ, designated Φ′, is a partial function defined as in (25).

(25) Delimitation of B by Φ′
Φ′(B) = B if B = Φ(B); otherwise, Φ′(B) is undefined

Under this formalization, suffixation of *-ŋgu* or *-ni* to minimal bases is regarded as the special, prosodically delimited case. Suffixation of *-gu* or *-ti* is regarded as a default, applicable whenever Φ′(B) is undefined (because B is greater than minimal).

The Dyirbal ergative, for example, consists of two morphological operations. One is 'Suffix *-ŋgu*', restricted prosodically by Φ′(MinWd). The other is prosodically unrestricted 'Suffix *-gu*', which is applicable elsewhere. If Φ′ returns a value, in accordance with (25), then *-ŋgu* is suffixed, since the target form is a foot/minimal word. But if Φ′ returns no value at all, then 'Suffix *-ŋgu*' cannot apply, and the default suffix *-gu* is provided instead. In general, a default operation need not be specified; in other languages, the responses to blocking of the prosodically delimited morphological operation are quite diverse, ranging from complete failure (in Kinande (Nandi) noun reduplication (Mutaka and Hyman, 1990) to zero affixation (in the Maori imperative; Hohepa, 1967) to syntactic periphrasis (in the English comparative). Such matters are outside the purview of prosodic circumscription theory.

In summary, three types of prosodic circumscription are subsumed under the parsing function Φ, which applies to define a prosodically delimited base within some morphological base. There are alternative ways of characterizing a prosodic base without Φ (McCarthy, 2000; McCarthy and Prince, 1993a, 1993b). Nonetheless, it seems clear that a notion akin to the prosodic base, common to all types of circumscription, must play a role in the analysis of phenomena such as those discussed here.

Proto-Algonkian Phonology and Morpho-Syntax

L Thomason, Smithsonian Institution, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

In 1925 Leonard Bloomfield reconstructed the common ancestor of the four best-attested Algonkian languages of the day – Fox (Meskwaki) [Mesquakie], Plains Cree, Menominee [Menomini], and Southern Ojibwa. These four languages, chosen by an accident of history, together retained reflexes of most of the important phonological and morphological distinctions of Proto-Algonkian. After work by Michelson (1935), Voegelin (1941), and Siebert (1941) established this unexpected fact, Bloomfield (1946), still drawing largely on examples taken from Fox, Cree, Menominee, and Ojibwa, sketched a description of Proto-Algonkian phonology and morphosyntax.

Proto-Algonkian Phonology and Morpho-Syntax

L Thomason, Smithsonian Institution, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

In 1925 Leonard Bloomfield reconstructed the common ancestor of the four best-attested Algonkian languages of the day – Fox (Meskwaki) [Mesquakie], Plains Cree, Menominee [Menomini], and Southern Ojibwa. These four languages, chosen by an accident of history, together retained reflexes of most of the important phonological and morphological distinctions of Proto-Algonkian. After work by Michelson (1935), Voegelin (1941), and Siebert (1941) established this unexpected fact, Bloomfield (1946), still drawing largely on examples taken from Fox, Cree, Menominee, and Ojibwa, sketched a description of Proto-Algonkian phonology and morphosyntax.

Table 1 Consonant clusters of Proto-Algonkian

	p	*k*	*t*	*č*	*s*	*š*	*θ*	*r*	*m*
p/k	—	—	ʔt	ʔč	ʔs	ʔš	ʔθ	ʔr	Hm[a]
h	hp	hk	ht	hč	hs	hš	hθ	hr[b]	
m/n	mp	nk	nt	nč	ns	nš	nθ	nr	
č	čp	čk							
s	sp	sk							
š	šp	šk	št[b]						
θ	θp	θk							
r	rp	rk							

[a]The reconstruction of the only cluster with *m* as second member is a guess; this cluster could equally well be *hm* as *ʔm*. The capital *H* in *Hm* substitutes for 'ʔ or *h*.'
[b]The reconstructions *hr* and *št* are each supported by only a single set of cognates.

Bloomfield's description, with a few emendations, has been confirmed and expanded by subsequent work on the history of the Algonkian language family.

Sound Inventory

Proto-Algonkian had eight vowels, two semivowels, and twelve consonants (eleven consonants phonemically). The vowels were short *i*, *e*, *o*, *a* and long *i:*, *e:*, *o:*, *a:*. The semivowels were *w* and *y*. The consonants were *p*, *t*, *č*, *k*, *s*, *š*, *m*, *n*, *θ*, *r*, *h*, and ʔ. Of these, ʔ existed in Proto-Algonkian only as an allophone of *p* and *k*.

The consonant clusters of Proto-Algonkian are given in Table 1. The first member of the cluster is listed in the column at the left, and the second member of the cluster is listed across the top of the table.

Note that in Proto-Algonkian nasals assimilate to the place of articulation of a following stop, and that the stops *p* and *k* reduce to ʔ before another consonant.

Meussen (1959) pointed out that ʔ was most likely the reflex of *p* and *k* as first member in a cluster. Pentland (1979) and Goddard (1994) argued for a trilled or tapped *r* in place of Bloomfield's *l*. Pentland (1979) first suggested the existence of *çp* as we as *çk*. Goddard (1994) argued for *sp*, *sk* in place of Bloomfield's *xp*, *xk* and *rp*, *rk* in place of Pentland's implied *çp* and Bloomfield's *çk*. Goddard (1974a) proposed the reconstruction *Hm*, a consonant cluster based on cognate sets missing from Bloomfield's analysis. In other respects, the reconstruction of the sound inventory of Proto-Algonkian is identical to that proposed in Bloomfield (1946).

Phonotactics and Morphophonology

Proto-Algonkian words began with a short vowel (other than *i* and *o*), a long vowel, or a simple consonant (other than *h*). Consonant clusters occurred postvocalically, exclusively. Semivowels (*w* and *y*) occurred intervocalically or after a consonant or consonant cluster.

Phonetically, all vowels were separated by a consonant, consonant cluster, or semivowel, and long vowels in word-final position were shortened by phonological rule. Vowel sequences produced by inflection or derivation were altered by phonological rule. Except that Goddard (1979: 72) first noted that initial syllables of Proto-Algonkian words excluded *o* as well as *i*, these observations date back to Bloomfield (1946).

In Proto-Algonkian, then, if we take V to represent any vowel, C any consonant, and G either semivowel, initial syllables had the shape V, CV, or CGV, with the additional restrictions that V could not be *i* or *o* and C could not be *h*. Medial and final syllables had the shape CV, CGV, CCV, CCGV, or GV, with restrictions on which consonant clusters could occur. Bloomfield also suggested that word-final long vowels were automatically shortened in Proto-Algonkian, but this has subsequently been shown not to be the case. See for instance Goddard (2003).

In inflection and derivation, a short vowel juxtaposed to a long vowel was typically deleted. A *y* semivowel was inserted between juxtaposed long vowels. The sequence *wo:* was replaced by *o:*; *wy* was replaced by *w*; *ti(:)* by *či(:)*; and *θi(:)* by *ši(:)* (Bloomfield, 1946).

In addition to a small number of regularly conditioned phonological rules, our reconstructions of Proto-Algonkian must include a large number of morphologically conditioned phonological rules. In some cases, attractive explanations of these rules have been put forward. For instance, Pentland has suggested that Pre-Proto-Algonkian contained both glottalized and plain series of consonants, and that the loss of the glottalized series caused a phonologically conditioned umlaut, *a:* → *e:* before glottalized consonants, to become morphologically conditioned umlaut: *a:* → *e:* before certain morphemes (see Pentland, 1999.) In other cases, the original conditioning factors of Proto-Algonkian morphophonology are still completely obscure. Proto-Algonkian appears to have run to contractions (a propensity which many of the daughter languages inherited). Bloomfield attempted to account for the various contractions of the sequence *awe* by suggesting that it contracted to *a:* before *t*, *k*, *s* and to *o:* before other consonants. The sounds *t*, *k*, and *s* form a somewhat ill-assorted phonetic class, and, in fact, Bloomfield's rule failed to hold up to further scrutiny. For the time being, we're left with having to list the individual cases where Proto-Algonkian *awe* contracted to *a:*,

contracted to *o:*, or failed to contract at all. Similarly, we must list the individual cases where *aye* contracted to *a:*, contracted to *e:*, or failed to contract.

In addition to morphophonological rules that affected both derivation and inflection, Proto-Algonkian had morphophonological rules that affected derivation but not inflection. At one extreme was the fairly regular rule (with a few marked exceptions) that a morpheme ending in a consonant or semivowel was separated from a following consonant by connective *i*. At the other extreme was a rule with a few marked instances: a tiny handful of morphemes beginning in *a:* or *e* triggered a process that replaced *ta:* and *te* by *sa:* and *se* (Bloomfield, 1946).

Word Formation

Proto-Algonkian words inflected as nouns, inflected as verbs, or were uninflected particles.

Nouns, verbs, and particles in Proto-Algonkian were either simple or complex. Complex nouns, verbs, and particles included one or more extra particles, termed prenouns if they attached to a noun, preverbs if they attached to a verb, and preparticles if they attached to a particle. Morphophonologically, these prenouns, preverbs, and preparticles behaved as independent words; morphosyntactically, they behaved as parts of the same word. In some cases, entirely distinct words, phrases, and even sentences intruded between the segments of such compound words.

Nouns, verbs, and particles in Proto-Algonkian formed diminutives (a process that affected the ends of stems), and verbs, particles, and a few nouns were reduplicated (a process that affected the beginnings of stems). These processes can be partially but not entirely reconstructed for Proto-Algonkian.

Noun Formation

Many Proto-Algonkian noun stems were single, unanalyzable morphemes. Other noun stems were more or less transparently composed from more than one morpheme. So, for instance, the noun stem *ši:ʔši:p-* 'duck' was a single morpheme, but the noun stem *erene ʔšip-* 'standard duck, mallard' was composed of a morpheme *eren-* meaning 'ordinary, plain' and a morpheme *-eʔšip* meaning 'duck'. Both *eren-* and *-eʔšip* occurred in other combinations. (Examples taken from Bloomfield, 1946.)

Bloomfield called the initial part of a stem the root, the final part of a stem the final suffix, and the medial part of a stem (if any) the medial suffix. In modern Algonkian terminology, stems are made up of initials, medials, and finals.

In Bloomfield's analysis, all noun stems consisted of at least an initial and a final. Bloomfield proposed phonetically null finals for noun stems such as *ši:ʔši:p-*. If the phonetically final element in a noun occurred elsewhere as a verb medial, as in the case of *šenkwa:skw-* 'pine tree' (*-a:skw-* 'tree' occurred as a medial in numerous verb stems), he analyzed the stem as an initial *šenkw-* plus a medial *-a:skw-* plus a null final.

Most modern Algonquianists would treat *ši:ʔši:p-* as an unanalyzable noun stem and *-a:skw* as a noun final with an independent life as a verb medial. In that case, it is possible to say that a Proto-Algonkian noun consisted at most of an initial and a final.

Initials and finals might themselves be complex. Many Proto-Algonkian initials and finals were transparently derived from noun stems or verb stems.

Bloomfield drew an important distinction between abstract finals, which merely indicated which grammatical category a stem belonged to, and concrete finals, which conveyed both grammatical and lexical information. Initials and medials in Proto-Algonkian were always more or less concrete. However, the internal structure of an initial, a medial, or a concrete final might contain an abstract part; for instance, the abstract *-w* that derived an initial from an animate intransitive verb stem.

Proto-Algonkian had a contrast between dependent and non-dependent noun stems, discussed in greater detail below. It also had contrasting sets of demonstratives, which constituted a morphologically and syntactically distinct class of inflected nouns.

Particle Formation

Particles formed a diverse class. However, most were composed of initial and final elements, and many were derived from nouns or from verbs.

Verb Formation

There were few unanalyzable verb stems in Proto-Algonkian. Verb stems were typically composed of an initial and a final, or an initial, a medial, and a final, or an initial, a medial, and two or more finals. Bloomfield made a distinction between primary and secondary derivation: in primary derivation, a final attached to an initial or an initial plus a medial; in secondary derivation, a final attached to a fully-formed verb stem.

Proto-Algonkian had a host of secondary finals. Among these were finals that derived applicatives from intransitive verbs; finals that derived ditransitives from ordinary transitive verbs; and finals that derived intransitive reflexives, reciprocals, passives, and middles from transitive or ditransitive verbs.

An interesting feature of Proto-Algonkian derivation was that intermediate stages of derivation did not necessarily have an independent existence.

This fact was duly noted by Bloomfield, who observed that the morphologically well-formed but semantically odd intransitive stem *wi:tapi-* 'sit with' is not attested in any Algonkian language, whereas two of its derivatives, transitive *wi:tapim-* 'sit with' and intransitive *wi:tapinke:-* 'sit with an indefinite person or people' (from derived transitive *wi:tapim-* plus a detransitivizing suffix *-ke:*) are widely attested.

Many initials, medials, and finals that were not derived from noun stems or verb stems nonetheless had a complex internal structure. Special terminology is required in these cases. Bloomfield employed the terms postradicals, premedials, postmedials, and prefinals to describe these sometimes obscure subparts of stems. So, for instance, the finals *-ači*, *-aten* in verb stems such as *kepači-*, *kepaten-* 'freeze solid' are made up of a concrete prefinal *-at-* 'freeze' and an abstract final *-i-* or *-en-* indicating which stem class the verb stem belongs to: intransitive taking an animate subject in the case of *-i-*, and intransitive taking an inanimate subject in the case of *-en-* (examples taken from Bloomfield, 1946).

Verb finals came in sets of as many as four: animate intransitive finals, which formed intransitive verbs taking an animate object; inanimate intransitive finals, which formed intransitive verbs taking an inanimate object; transitive animate finals, which formed transitive verbs taking an animate object; and transitive inanimate finals, which formed transitive verbs taking an inanimate object.

A special class of Proto-Algonkian morphemes which occurred both as verb initials and as preverbs added a valence to a verb stem. The valence then required a complement. For instance, Proto-Algonkian initial *taθ-*, preverb *taši* meant 'there'. Any verb *taθ-* or *taši* appeared in had to have a locative complement, which also had to precede its valence-bearer in the clause.

Noun Inflection

Unpossessed, nonvocative, nonlocative nouns in Proto-Algonkian inflected for number, gender, and prominence.

Number was singular or plural.

Gender was animate or inanimate. Grammatical gender is of course not entirely predictable: as Bloomfield observed, Proto-Algonkian marked 'raspberry' and 'calf of the leg' as animate but 'strawberry' and 'thigh' as inanimate.

Prominence (marked on animate nouns only) was proximate or obviative. A proximate third person is the most interesting third person in the universe of reference; an obviative third person is a person eclipsed by some proximate third person in the universe of reference. The strict rule of prominence in Proto-Algonkian nouns was that an obviative noun could be possessed by a proximate or obviative person, but a proximate noun could only be possessed by a non-third person.

Possessed, nonvocative, nonlocative nouns in Proto-Algonkian inflected for number, gender, prominence, and type of possessor.

The prefix *we-* attached to nouns possessed by a third person possessor. The prefix *ke-* attached to nouns possessed by a second person singular, second person plural, or inclusive possessor. The prefix *ne-* attached to nouns possessed by a first person singular or exclusive possessor. (Inclusive is English 'we' meaning 'I and you (and others)'; exclusive is English 'we' meaning 'I and other(s) but not you.')

Nouns possessed by a plural, obviative, or indefinite possessor took a suffix in addition to a prefix. Nouns possessed by a second person plural or third person plural possessor took the suffix *-wa:w*; nouns possessed by an inclusive possessor took the suffix *-enaw*; nouns possessed by an exclusive possessor took the suffix *-ena:n*; nouns possessed by an obviative third person took the suffix *-iriw*; nouns possessed by an indefinite possessor took the suffix *-inay*.

Many nouns also took a possessive marker *-em*. This suffix preceded the plural or obviative possessor marker, if any.

Certain noun stems in Proto-Algonkian required possession and never occurred unpossessed. These dependent noun stems contrasted with non-dependent noun stems, which could occur both possessed and unpossessed. Prominent classes of dependent nouns were kinship terms and terms for body parts.

Some dependent nouns, such as terms for body parts, could form non-dependent derivatives. These derivatives took a prefix *me-* to indicate indefinite possession by a human, or the ordinary third person prefix *we-* to indicate indefinite possession by an animal.

Vocative nouns took a vocative suffix which inflected as singular or plural. Vocative nouns could also inflect for a first person possessor.

Locative nouns took a locative suffix. They could inflect for any kind of possessor.

Some of the possibilities for Proto-Algonkian noun inflection are given in Table 2. The *-em* included in the possessed forms has a lexicalized pattern of occurrence: it was obligatory with some possessed Proto-Algonkian nouns, optional with others, and impermissible with still others.

Bloomfield originally reconstructed *-ena:n* for the inclusive possessive marker as well as the exclusive possessive marker. He reconstructed *-eliw* for the

Table 2 Proto-Algonkian noun inflection

animate obviative pl.	—ahi	*3 obviative*	we—emiriwahi
inanimate sg.	—i	*3 sg.*	we—emi
inanimate pl.	—ari	*3 pl.*	we—emwa:wari
locative	—enki	*indefinite*	we—eminay + enki[a]

[a] This combination was subject to contraction.

obviative possessor marker, and gave no reconstruction for the indefinite possessor marker. He treated locative nouns as particles (locative nouns behaved in some respects like particles, and in some respects like nouns), and made no mention of possessed vocative and locative nouns. In other respects, our basic understanding of Proto-Algonkian noun inflection is unchanged since Bloomfield's 1946 sketch.

See Goddard (1979: 86–87) for a discussion of *-ena:n* and *-enaw* and *-eliw* versus *-iliw* (here *-iriw*). See Goddard (1995: 125–126) for a discussion of Proto-Algonkian *-inay*.

Verb Inflection

Three Orders of Moods

All Proto-Algonkian verbs inflected for mood. In addition, animate intransitive (AI) verbs inflected for an animate subject. Intransitive inanimate (II) verbs inflected for an inanimate subject. Transitive animate (TA) verbs inflected for an animate or inanimate subject and an animate object. Transitive inanimate (TI) verbs inflected for an animate or inanimate subject and an inanimate object.

Some verbs of Proto-Algonkian that inflected as transitives (TIs, in every case) behaved semantically as intransitives. Based on the evidence of his four core daughter languages, Bloomfield also reconstructed Proto-Algonkian verbs that inflected as intransitives but behaved semantically as transitives. As it happens, the Proto-Algonkian ancestors of these verbs – animate intransitive verbs, in shape – sometimes inflected for objects as well as a subjects. More on this below.

Ditransitives, like other Proto-Algonkian TAs, inflected for a subject and for a single object (the indirect object or goal). A special suffix attached to ditransitive stems to mark the existence of the second object, but gave no information about its person, number, gender, or prominence.

Proto-Algonkian verbal inflection fell into three orders of moods, distinguished by three types of inflection: a set of independent order moods, a set of conjunct order moods, and an imperative mood.

The independent order moods inflected with prefixes and suffixes. The conjunct and imperative moods inflected with suffixes only.

All moods marked prominence. The strict rules of prominence in Proto-Algonkian verbs were: (1) two third persons indexed on the same verb differed in rank; (2) cases of a low-ranked person acting on a high-ranked person were marked as inverse transfers of action.

Proto-Algonkian verbal inflection distinguished three degrees of prominence for animate third persons (proximate, obviative, and secondary obviative), and two degrees of prominence for inanimate third persons (proximate and obviative). Inanimates juxtaposed to animates were not marked for prominence. Obviatives juxtaposed to non-obviatives were never marked as secondary obviative. Obviatives juxtaposed to non-third persons are sufficiently rarely attested in the daughter languages that we may guess they were rare in Proto-Algonkian as well; in any case, we are unable to reconstruct a full set of forms for these transactions.

The three orders of moods treated inverse transactions differently. The imperative mood did not permit inverse transfers of action. The independent order marked as inverse all cases of an indefinite subject acting on a non-third person, a third person acting on a non-third person, an obviative acting on a proximate, a secondary obviative acting on primary obviative, and an inanimate acting on an animate. The conjunct moods marked as inverse cases of low-ranked third persons acting on high-ranked third persons: an obviative acting on a proximate, a secondary obviative acting on a primary obviative, and an inanimate acting on an animate third person.

The basic ingredients of these observations about Proto-Algonkian verb inflection were first laid out in Bloomfield (1946). However, Bloomfield originally proposed five orders of moods, two of which (the prohibitive and interrogative) were subsequently reanalyzed as belonging to the conjunct order. Also, the intransitive and ditransitive second object marker was first reconstructed by Goddard (1974b).

Independent Order Moods

In Proto-Algonkian, in addition to the two kinds of prominence marking already mentioned – proximate/

2p	ke—a:Hmwa		ke—eko:Hmwa	ke—ekwiHmwa
3p	—e:waki (-3')	—eko:ki	—a:waki	—ekwiwaki
	TI objective	*TI absolute*	*AI*	*II*
	-0(')s	-0(')		
1s	ne—a:ni	ne—a	ne—	—wi (0s)
2s	ke—a:ni	ke—a	ke—	—wari (0p)
3s	we—a:ni	—amwa	—wa	—riwi (0's)
1p	ne—a:na:ni	ne—a:Hmena	ne—Hmena	—riwari (0'p)
12	ke—a:nawi	ke—a:Hmena	ke—Hmena	
2p	ke—e:wa:wi	ke—a:Hmwa	ke—Hmwa	
3p	we—e:wa:wi	—amo:ki	—waki	

obviative marking of third persons in transitive and intransitive verbs, and inverse marking of certain transitive verbs – the independent order distinguished two types of objects for transitive verbs. Goddard (1979: 87–88), invoking the evidence of the daughter languages that preserved both sets of independent inflection (not found in Fox, Cree, Menominee, but with relics in Ojibwa), suggested that in Proto-Algonkian the objective set was used in clauses where the verb had a definite noun or pronoun as object, while the absolute set was used in clauses where the verb had an indefinite noun as object or (in the case of AIs and objectless TIs) had no object.

The Independent Indicative Mood

Partial paradigms for the independent indicative mood are given in Table 3. Table 3 is adapted from Goddard (1967). Most of the forms involving an obviative participant or a third person plural participant have been omitted from this table, as have object-agreement forms for AIs. See Pentland (1999) for a much fuller treatment of independent inflection that reaches some different conclusions.

First person singular and first person exclusive are represented as 1s, 1p; second person singular and plural as 2s, 2p; second person unspecified for number as 2; inclusive as 12; third person animate proximate singular and plural as 3s, 3p; third person animate obviative singular as 3's; third person animate obviative unspecified for number as 3'; third person inanimate proximate singular and plural as 0s, 0p; third person inanimate obviative singular and plural as 0's, 0'p; third person inanimate singular unspecified for proximacy as 0(')s; third person inanimate unspecified for number or proximacy as 0(''); indefinite as X.

Note that most of the independent inflections involved both a prefix and a suffix. The prefix was *ke-* if there is a second person participant in the verb, *ne-* if there was a no second person but a first person participant in the verb, and *we-* for transitive objective inflections if there was no non-third person participant in the verb. Intransitive and TA absolute inflections took no prefix, and intransitive 1s and 2s forms took no suffix.

The intransitive suffixes for the Proto-Algonkian independent order consisted of a person marker. The person marker was null for singular non-third person subjects, *-w* plus the appropriate noun ending for third person subjects, *-Hmena* for 1p and 12, *-Hmwa* for 2p.

3's-0(')	—amirite:	*0(')-1s*	—ike:		
X-0(')	—amenke:	*0(')-1p*	—iyamenke:		

In addition, an obviative marker *ri* preceded *w* in the marking for inanimate obviative subjects.

The transitive suffixes in Table 3 consist of a theme sign followed by person markers. The theme sign was *-a:* or *-e:* for TA direct (high-on-low) transfers of action, *-ekw* for inverse (low-on-high) transfers of action, *i* for second person acting on first person, *-eθ* for first person acting on second person, *-a:* or *-e:* for TI objective transfers of action, and *-a:* or *-am* for TI absolute transfers of action. The person markers were in some cases again null for singular non-third person participation in the verb, *-w* plus an appropriate noun ending for third person participation in the verb, *-Hmena* for 1p and 12 participation in the verb, *-Hmwa* for 2p participation in the verb. In other cases, plural participation in the verb was indicated by the same morphemes used for plural possessor marking of nouns: *-wa:w*, *-enaw*, *-ena:n*.

The paradigms in Table 3 look strikingly different from those given in Bloomfield (1946). However, most of the changes can be traced to Goddard's reconstruction of the opposition between absolute and objective inflections for TAs and TIs. The evidence of the Eastern Algonkian languages that Bloomfield had little access to – Munsee and Unami Delaware, Mahican, and Western Abenaki [Abnaki, Western] – provided a solution for the confusing divergence of forms exhibited by Bloomfield's stock four languages. Note that Table 3 also exhibits the minor substitution of *r* for Bloomfield's *l*.

Other Independent Moods

The independent indicative mood is the best-established mood of the independent order. We know that Proto-Algonkian had other independent moods, but we know little about them. All the lesser independent moods inflected much like the independent indicative, but with a suffixed mood marker added to every form. Goddard (1979) observed that both the independent and conjunct orders of Proto-Algonkian seem to have included a mood marked by *-(e)pan* and another mood marked by *-(e)san*. The *-(e)pan* moods may have been perfective or preterite and the *-(e)san* moods may have been imperfective or present, but the exact nature of the contrast is difficult to determine on the basis of the available evidence. See Goddard (1995) and Pentland (1999) for a discussion of these moods.

Conjunct Order Moods

The conjunct order moods inflected with suffixes combined in some cases with modification of the first element of the word ("initial change"). The person markers of the conjunct order differed drastically from those of the independent order.

The Conjunct Subjunctive Mood Partial paradigms for the conjunct subjunctive are given in Table 4. Again, many of the forms involving obviatives and plurals are omitted.

Note that the basic conjunct inflection is exclusively suffixing. The subjunctive mood was chosen to illustrate the conjunct paradigms because the mood marker for the best-attested mood of the conjunct order (conjunct indicative, for Bloomfield; aorist, for Goddard) is word-final *-i*. Word-final *-i* inconveniently triggers palatalization in suffixes ending in *-t*. By contrast, the mood marker for the subjunctive, observable in every form in Table 4, is a non-palatalizing word-final *-e:*.

The intransitive suffixes for the Proto-Algonkian conjunct order consisted of a person marker followed by a mood marker. The person marker was *-a:n* for 1s, *-an* for 2s, *-a:nk* for 1p, *-ankw* for inclusive, *-e:kw* for 2p, *-t* or *-k* for third person animates, *-k* for inanimates, and *-(e)nk* for the indefinite. Animate plurals inserted a marker *-wa:* before or after the third person marker; animate and inanimate obviatives inserted a marker *-ri* before the third person marker.

Transitive inanimate suffixes for the conjunct order consisted of a theme sign *-am*, followed (potentially) by a 3p marker *-wa:* or an obviative marker *-ri*, followed by one of the same set of person markers used in conjunct AIs and IIs, followed by a mood marker.

Transitive animate suffixes for the conjunct order consisted of a theme sign followed by a person marker or person markers followed by a mood marker. The direct theme sign *-a:* indicated the presence of an animate third person object (in other than inverse situations. Also, note that *-a:* dropped before a vowel: cf. Goddard, 1979: 110); the theme sign *-eθ* indicated the presence of a second person or inclusive object; the theme sign *-i* indicated the presence of a first person object; the inverse theme sign indicated a low-on-high third person-on-third person transfer of action. As can be seen from Table 4, the principles governing the exact choice of person marker, and the insertion of suffixes marking animate plural, obviative, inanimate, and indefinite involvement, were quite complex.

The basic inventory of conjunct inflections was established by Bloomfield (1946). However, nearly all the inanimate-subject and indefinite-subject forms were supplied by Goddard (1979). There is dubious or entirely insufficient evidence for many of the 3p and obviative forms which ought to round out these paradigms. And again, *r* has been substituted for Bloomfield's *l*.

Other Conjunct Moods A large number of conjunct moods can be confidently reconstructed for Proto-Algonkian. Among these are the aorist and the subjunctive, which have already been mentioned; the prohibitive, future imperative, and potential, which Bloomfield originally assigned to a prohibitive order; the interrogative, which Bloomfield originally assigned to an interrogative order; the changed conjunct, which employed the same mood marker as the aorist but also altered the initial vowel of the verb (instituting initial change); the iterative, which employed its own mood marker – basically, the inanimate plural version of the aorist and changed conjunct marker – along with initial change; and a large host of aorist or interrogative participles, marked by modified nominal endings and by initial change. See Bloomfield (1946) and Goddard (1979) for a brief discussion of these moods.

Table 5 Partial paradigm for the Algonkian imperative

	AI		*TA*
2s	—ro	*2s-1s*	—iro
2p	—ko	*2p-1s*	—iko
		2-1p	—ina:nke
	TI	*2s-3*	—i
2s-0(')	—anro	*2p-3*	—ehko
2p-0(')	—amoko		

The Imperative Mood

A partial paradigm for the imperative is given in Table 5.

Note that the imperative inflection is exclusively suffixing, and that the person markers are entirely different from those of the independent and conjunct orders.

The imperative paradigm given in Table 5 is taken directly from Bloomfield (1946). (Note that Bloomfield's *o* could be *we*.) The subject is second person in every case; the object is first person, animate proximate third person, or inanimate third person. In many of the daughter languages, these second person subject forms exist alongside inclusive subject (hortative) and third person subject (optative) forms. However, as of this date, there is no agreed-upon reconstruction of these forms for Proto-Algonkian. See Goddard (1979) for a brief discussion of the hortative imperatives.

Proto-Bantu

J Maho, Gothenburg University, Gothenburg, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The Bantu languages are spoken in an area south of an imaginary line drawn from central Cameroon to southern Somalia, covering roughly a third of the African continent. They constitute the largest individual language grouping in Africa, and comprise anywhere between 300 to 600 distinct languages.

The rather remarkable structural similarities among the large majority of the Bantu languages have since long been recognized, and often also exaggerated. Thus, unfortunately, the label 'Bantu' has oftentimes been used as if it referred to one single language.

The relatively close internal affinity of the Bantu languages was already recognized during the 18th century by some of the early missionaries. The first major comparative work on the Bantu languages was done by Wilhelm Bleek during the second half of the 19th century. His work was soon followed by others, most notably Carl Meinhof, whose philological legacy for Bantu studies can hardly be underestimated. Most of his publications on comparative Bantu have stood the test of time fairly well.

If one name should be singled out in the modern era of Bantu historical linguistics, it would have to be that of Malcolm Guthrie, whose contributions to comparative Bantu started in the 1940s, and eventually culminated in his *magnum opus*, the four-volume *Comparative Bantu* (1967–1971). This has become one of the most widely referred- to titles in the entire field of Bantu studies (historical or otherwise). It contains a number of things which are of interest to the comparative/historical linguist. There is a list of some 700 suggested Proto-Bantu roots, a huge amount of proposed sound changes linking forms in individual Bantu languages with Proto-Bantu, a history outline for the development of the Bantu languages (although this particular part is severely outdated by now), and many other things. Two of the volumes are taken up by systematic collections of various lexical and grammatical items based on form–meaning similarities. These are organized in some 2500 'comparative series' (as Guthrie called them), each preceded by a starred form. Somewhat confusingly, however, these starred forms were not offered as reconstructions, even though they have generally been treated as such by many Bantuists.

Comparative Bantu also contains Guthrie's latest version of his now-famous (referential) classification, in which Bantu languages are assigned to various 'zones' (labeled with capital letters), within which

Introduction

The Bantu languages are spoken in an area south of an imaginary line drawn from central Cameroon to southern Somalia, covering roughly a third of the African continent. They constitute the largest individual language grouping in Africa, and comprise anywhere between 300 to 600 distinct languages.

The rather remarkable structural similarities among the large majority of the Bantu languages have since long been recognized, and often also exaggerated. Thus, unfortunately, the label 'Bantu' has oftentimes been used as if it referred to one single language.

The relatively close internal affinity of the Bantu languages was already recognized during the 18th century by some of the early missionaries. The first major comparative work on the Bantu languages was done by Wilhelm Bleek during the second half of the 19th century. His work was soon followed by others, most notably Carl Meinhof, whose philological legacy for Bantu studies can hardly be underestimated. Most of his publications on comparative Bantu have stood the test of time fairly well.

If one name should be singled out in the modern era of Bantu historical linguistics, it would have to be that of Malcolm Guthrie, whose contributions to comparative Bantu started in the 1940s, and eventually culminated in his *magnum opus*, the four-volume *Comparative Bantu* (1967–1971). This has become one of the most widely referred- to titles in the entire field of Bantu studies (historical or otherwise). It contains a number of things which are of interest to the comparative/historical linguist. There is a list of some 700 suggested Proto-Bantu roots, a huge amount of proposed sound changes linking forms in individual Bantu languages with Proto-Bantu, a history outline for the development of the Bantu languages (although this particular part is severely outdated by now), and many other things. Two of the volumes are taken up by systematic collections of various lexical and grammatical items based on form–meaning similarities. These are organized in some 2500 'comparative series' (as Guthrie called them), each preceded by a starred form. Somewhat confusingly, however, these starred forms were not offered as reconstructions, even though they have generally been treated as such by many Bantuists.

Comparative Bantu also contains Guthrie's latest version of his now-famous (referential) classification, in which Bantu languages are assigned to various 'zones' (labeled with capital letters), within which

languages are further subclassified into groups (labeled with digits in tens). This has yielded unique labels for individual Bantu languages. Thus, for instance, Kikongo (Kongo) is referred to by the code H16 (= zone H, group 10, language 6), Zulu by S42, Swahili by G42, etc. Guthrie's zones and groups have a strong geographic bias, while their values as historically valid groupings range from good to none at all. Thus, it is a referential classification, first and foremost.

Proto-Bantu Sounds

The sound system of Proto-Bantu is by most accounts a simple one. There were seven vowels (which can/could be either short or long) and some 10-plus consonants. In addition, there were likely two tones, high and low.

In the Bantu literature, high vowels **i* and **u* are occasionally referred to as 'superhigh' or 'superclose,' and the symbols <i̧> and <u̧> respectively are commonly used. Similarly, **ɪ* and **ʊ* are often represented by the symbols <i> and <u> respectively (see Table 1). The assumed phonetic values of the high vowels were presumably nothing extraordinary, however, so they seem best represented by the standard IPA symbols. Most modern Bantu languages have vowel systems differing from the original Proto-Bantu one. Even some of the modern seven-vowel systems seem to have gone through some minor restructuring (see Hyman, 1999). While seemingly only a handful of languages have developed more complex vowel systems, many Bantu languages (in particular the large majority of languages spoken below the rain forest area) have instead developed five-vowel systems by merging the two highest series of vowels, **i* = **ɪ* and **u* = **ʊ*.

Minimal pairs based on vowel length alone include, for instance, **bàbá* 'wing' vs. **bààbá* 'father.' It has been suggested that, as in many modern Bantu languages, only short vowels were possible word finally, while only long vowels were allowed before prenasalized consonants; or rather, "we cannot demonstrate any quantity opposition in Proto-Bantu word-finally or preceding a nasal complex" (Meeussen, 1972: 2).

Proto-Bantu has been reconstructed as a two-tone language, employing high and low. Minimal pairs based on tonal profile alone include, for instance, **kádá* 'crab' vs. **kádà* 'ember(s), charcoal' (see Greenberg, 1948).

Table 1 Reconstruction of the Proto-Bantu vowel system

**i* ⟨i̧⟩		**u* ⟨u̧⟩
**ɪ* ⟨i⟩		**ʊ* ⟨u⟩
**ɛ∼e* ⟨e⟩		**ɔ∼o* ⟨o⟩
	**a* ⟨a⟩	

Table 2 Three reconstructions of the Proto-Bantu consonant system

Carl Meinhof (1932)			
m	*n*		*(ŋ)*
p	*t, t^j*		*k, k^j*
β			*ɣ, ɣ^j*
w	*l, l^j*	*j*	
Malcolm Guthrie (1967–1971)			
m	*n*	*ɲ*	*ŋ*
p	*t*	*c*	*k*
b	*d*	*ɟ*	*g*
		j	
Achille Meeussen (1967), currently favored			
m	*n*	*ɲ*	*(ŋ)*
p	*t*	*c∼s*	*k*
b	*d∼l*	*j∼z∼j*	*g*
mp	*nt*	*ɲc*	*ŋk*
mb	*nd*	*ɟ*	*ŋg*

The reconstructed Proto-Bantu consonants (see Table 2) form a relatively simple set, comprising three or four nasals and eight plosives, which latter can also be prenasalized. The lack of fricatives in the currently favored reconstruction(s) may look odd at first sight, but languages without fricatives (on a phonemic level) do exist, albeit they seem to be unusual. However, the plosives **c*, **ɟ*, and **d* are thought to have had the alternative (allophonic) nonplosive realizations **s*, **z* (or **j*), and **l*, respectively. In general, fricatives and affricates in the modern Bantu languages can usually be derived from historical plosives by way of a process commonly known as spirantization (see below).

Important Sound Changes

A number of important sound changes have been established for various subregions of the Bantu area.

Meinhof's rule (also known as the Ganda law) deletes the plosive of a nasal + plosive-commencing syllable when this is immediately followed by another nasal (+plosive)-commencing syllable. It can be schematized as follows:

$$\text{NCVN(C)V} \rightarrow \text{N(N)}\tilde{\text{V}}\text{N(C)V}$$
$$(\text{C} = \text{plosive})$$

In Ganda, for instance, an underlying /n-lima/ 'I cultivate' realizes as [nnima] (cf. Proto-Bantu **-dìm-*),

Table 3 Spirantization (frication) involving high front vowels (adapted and simplified from Hyman, 2003)

*pi	>p^hi	>pfi		>fi
		>psi	>tsi	>si
*bi	>b^hi	>bvi		>vi
		>bzi	>dzi	>zi
*ti	>t^hi	>tsi		>si
*di	>d^hi	>dzi		>zi
*ci	>c^hi			>si
*ji	>$ɟ^h$i			>zi
*ki	>k^hi	>ksi	>tsi	>si
*gi	>g^hi	>gzi	>dzi	>zi

while /en-ganda/ 'clan' (preceded by a noun class marker) is realized as [eŋŋãnda] (cf. *ŋgàndá).

The Kwanyama law affects medial *mb-/nd-* commencing syllables by eliminating their nasality in contexts where these are immediately preceded by nasal + plosive-commencing syllables. It can be stated as follows:

NCVndV → NCVdV
NCVmbV → NCVbV
(C = plosive)

Thus in Kwanyama, where this sound change was first attested, we find *ongobe* 'cattle,' which derives from *ŋgòmbè.

Dahl's law, found in the eastern Bantu area, is a dissimilation process changing voiceless [k] to voiced [g] when the following syllable begins with a voiceless consonant. Thus, schematically it would look like this:

kVC̥V → gVC̥V

In Gikuyu, where Dahl's law is still productive, an underlying /kekombɛ/ 'cup' is realized as [gekombɛ]. Historical traces of Dahl's law can be found in Jita, where *òkwìigútá* 'be full, satiated' derives from *-*ɟíkʊt-*.

One of the most widespread sound changes, and which has affected a multitude of the Bantu languages below the forest area (though by no means all), goes by the name of spirantization (also known as frication). This has caused historical plosives to 'deplosivize' in contexts where they have been immediately followed by the high vowels *i and *u (or *i̯ and *u̯, in Bantuist jargon). Thus their modern reflexes are either affricates, fricatives, approximants, or even zero (see Table 3). Examples of spirantization effects abound across the Bantu area, as in the following examples from Swahili:

-fika 'arrive' ← *-*pìk-*
-fisi 'hyena' ← *-*píkí-*
-vuma 'roar' ← *-*dùm-*
-vunja 'break' ← *-*búɲ-*

It should be noted, however, that "while such frications occur frequently throughout the Bantu zone, there is considerable variation. Not only can the exact reflexes differ, but so can the environments in which they occur" (Hyman, 2003: 54).

It should here be noted that none of the sound rules discussed in the literature on Bantu languages have been much use in establishing an overall subgrouping of the Bantu languages (for which see below).

Lexical Reconstructions

Currently there exists a database with some 10 000 reconstructed Proto-Bantu words (not roots). This collection is commonly referred to as BLR3, which stands for *Bantu Lexical Reconstructions 3* (Bastin *et al.*, 2003), and is available as a searchable database on the Internet. The first version was compiled by Achille Meeussen in 1969 at Tervuren, Belgium, while a computer-readable second version dated 1998 is still distributed as a FileMaker file via the Comparative Bantu Online Dictionaries website.

The contents of BLR3 comprises the collected efforts of more than 100 years of reconstruction work by Carl Meinhof, Lilias Homburger, Walther Bourquin, Joseph Greenberg, Achille Meeussen, Malcolm Guthrie, Yvonne Bastin, André Coupez, and many others (see Table 4). The actual number of unique roots in BLR3 is much lower than 10 000. The current version recognizes 1400 unique roots with an additional 3000 derivative and/or variant forms. The rest are uncategorized/unsorted as yet. Many of the starred items have modern reflexes covering a wide geographical area, and can presumably also be projected back to Proto-Bantu. Presently, this adds up to some 1200 reconstructed items. Most of the entries, however, have highly restricted geographical distributions and may thus represent post-Proto-Bantu forms.

The semantics of many reconstructed items and their relationships with each other still need some amount of work. Schadeberg (2002) exemplified some of this ongoing work, and proposed a semantic chain comprising *-*kòt-* 'stoop, be bent' → *-*kòt-* 'be old' → *-*kòté* 'old man' → *-*kòtà* 'chief,' and thereby also showed how order can be brought to an otherwise unsorted collection of lexical reconstructions.

Grammatical Reconstructions

The grammar of Proto-Bantu was most likely very much like that found in most modern Bantu languages, which entails a basic word order of subject–verb–object, a complex noun class system with an elaborate agreement morphology, a set of so-called verbal extensions (see below), and so on. Many

Table 4 Selected Proto-Bantu reconstructions (BLR3) with wide-spread reflexes

[a]The Balundu data comes from Kuperus (1985).
[b]The Gweno data comes from Philippson and Nurse (2000).
[c]The Tswana data comes from Snyman *et al.* (1990).
The original orthography is slightly changed here.

of the relevant Proto-Bantu grammatical morphemes have been offered reconstructions by Carl Meinhof (1948), Achille Meeussen (1967), and others.

In modern Bantu languages, we can usually find some 10 to 20 noun classes (genders). These are overtly realized as prefixes on nouns and a variety of agreement markers elsewhere, both in and outside the noun phrase. Twenty or so noun classes and their associated nominal prefixes are usually accepted for Proto-Bantu (see Table 5), but adding all putative suggestions made in the literature, the total might run up to 30, or even beyond.

As the noun class prefixes are simultaneously markers of grammatical number (where relevant), they usually pair into singular/plural pairings. The full set of possible pairings has not been reconstructed, however, as there exists, besides a central chunk of similarities, a wide variation in the modern Bantu languages.

Table 5 The Proto-Bantu noun class system[a]

Noun class	*Noun prefix*	*Assumed semantics*[b]
1	**mʊ̀-*	Humans
1a	*ø-*	Kin, personified animals
2	**bà-*	Plural of class 1
3	**mʊ̀-*	Trees, plants, inanimates
4	**mì-*	Plural of class 3
5	**ì-*	Miscellaneous, augmentatives
6	**mà-*	Plural of classes 5, 11, 14, 15
7	**kì-*	Things, artifacts, augmentatives
8	**bì-*	Plural of class 7
9	**ɲ̀-*	Animals
10	**ɲ̀-*	Plural of class 9
11	**dʊ̀-*	Long thin things
12	**kà-*	Small things, diminutives
13	**tʊ̀-*	Plural of class 12
14	**bʊ̀-*	Abstracts, mass nouns
15	**kʊ̀-*	Infinitives, some body parts
16	**pà-*	Locatives (near, explicit)
17	**kʊ̀-*	Locatives (remote, general)

23	**ì-*	Locative (unspecified)

[a]The morphemes are given here as they are reconstructed by Meeussen (1967). The numbers derive from a commonly used numbering system in Bantu studies that has been devised for easy reference when comparing differing forms across several languages. (Numbers 20, 21, and 22 are used for a set of classes that have since been delected from the Proto-Bantu inventory.)
[b]The assumed semantics given here are only rough indicators. all noun classes usually include small or large amounts of miscellaneous nouns.
Reconstructed singular/plural pairings 1/2, 1a/2, 3/4, 5/6, 7/8, 9/10, 11/6, 11/10, 12/13, 14/6, 15/6.

It is usually possible to associate individual noun classes with semantic parameters. For instance, nouns referring to humans are commonly categorized in a class deriving from Proto-Bantu class 1 (see Table 5). Even though there are many language-specific idiosyncrasies in terms of noun class semantics, some general tendencies can be found. These crosslinguistic similarities are often projected back to the semantic makeup of the Proto-Bantu noun class system. One of the most widely cited contributions in this area was presented by Chet Creider and Peter Denny in the mid-1970s (see Denny and Creider, 1986). They reconstructed a noun class system in which an initial distinction is made between mass nouns and count nouns. The latter are then subdivided according to various configurational and shape-related features, such as 'animate' vs. 'artefact,' 'solid' vs. 'outline,' 'extended' vs. 'nonextended,' etc. Thus, nouns belonging to Proto-Bantu class 5 are semantically characterized by being units (singular) of nonextended, solid figures, such as **-bádà* 'spot, freckle,' **-béèdè* 'breast,' **-bʊ̀bì* 'spider,' and others. The system that emerges from this model is a very

well-organized one, and it may be worth pointing out that no modern Bantu language exhibits such a neat system, even though the basic tendencies are there in most of them.

The morphological makeup of a Proto-Bantu verb probably looked like this (see Meeussen, 1967):

NEG + SUBJ + NEG/TAM + OBJ + ROOT + EXT + SUF

The above formula is a simplified version of what is possible in most modern Bantu languages. (Not all slots are obligatorily filled, and some may have multiple contents, especially the medial NEG/TAM slot.) Besides agreement markers for subject (SUBJ) and, optionally, object (OBJ), there are slots also for one or several tense–aspect–mood (TAM) and/or negation (NEG) markers. In addition, the verb root may be suffixed with a so-called verb extension (EXT), which in one way or another affects the semantics of the root (see more below). All Proto-Bantu verbs are reconstructed with a final consonant (e.g., -CVC-), and as the phonotactic rules of the Bantu languages require vowel-ending words, a final suffix (SUF) usually consisting of a single vowel, most commonly *-*a*, is required to fulfill the morphological makeup.

The complex paradigm of assumed agreement markers that must have existed in the Proto-Bantu grammar has also been reconstructed. While some modern Bantu languages allow for several object markers to appear simultaneously, it is unclear whether or not this was possible in Proto-Bantu. Possibly it was, but we do not know. The first and second person pronominal markers have been reconstructed as follows: 1SG **ǹ-* (SUBJ)/**-ǹ-* (OBJ), 1PL **tʊ̀-/*-tʊ́-*, 2SG **ḱ-/*-kʊ̀-*, and 2PL **mʊ̀-/*-mʊ̀*. The third person pronominals comprise distinct markers for each individual noun class. With a few exceptions, these are segmentally identical to the noun class prefixes but appear here generally with high tones instead of low tones. The reflexive marker **-í-*, appearing in the OBJ slot, is used for all persons and classes.

As for TAM markers, there is still much work to be done. In modern Bantu languages, tense-aspect markers often consist of short (C)V syllables. Thus, form–meaning similarities simply due to change is a high-risk factor. Meeussen (1967) suggested a whole range of Proto-Bantu TAM markers, such as the preverbal markers for the negative **ká-/*tá-* and **-tá-/-tí-*, the recent past tense **-a-*, the preterite or remote past **-á-*, the conditional **-ngá-*, the persistive **-kí-*, as well as suffixes for the past/perfect **-ide*, the indicative (or rather, 'mood neutral') **-a*, the subjunctive **-e*, and others.

In modern Bantu languages, there is widespread use of so-called verb extensions. Many of these have also been reconstructed for Proto-Bantu, for instance, the passive **-ib(ʊ)-*, the applicative/dative **-ɪd-* (or **-ɪl-*), the causative **-(ic)i-*, the reciprocal **-an-*, the stative **-am-*, the reversive/separative **-ʊk-* and **-ʊd-* (or **-ʊl-*), impositive **-ik-*, and others. In BLR2/3, one can find numerous reconstructed words containing one or other of these extensions, as in the following examples:

**-báb-ʊk-* 'be singed/burned' ← **-báb-* 'singe, burn'
**-còk-ʊd-* 'pull out' ← **-còk-* 'poke in, put in'
**-dáad-ɪk-* 'invite, convoke' ← **-dáad-* 'lie down, sleep, spend night'
**-dàg-an-* 'promise each other' ← **-dàg-* 'promise, foretell'

The following examples illustrate some of the word class-changing derivational suffixes reconstructed for Proto-Bantu:

**-ɟíb-ì* 'thief' ← **-ɟíb-* 'steal'
**-kúm-ì* 'rich person' ← **-kúm-* 'be honored, be rich'
**-cèk-ò* 'laughter' ← **-cèk-* 'laugh, joke'
**-ɟímb-ò* 'song, dance' < **-ɟím* 'dance, sing'
**-bîɪ-p-* 'be bad' ← **-bîɪ-* 'bad'
**-néne-p-* 'be big' ← **-nénè* 'big'

Grammatical morphemes in modern Bantu languages originate in lexical items by way of so-called grammaticalization. In the overwhelming majority of cases, their lexical sources must be placed at a stage long before the presumed existence of Proto-Bantu. However, one clear example of a Proto-Bantu lexical item that has grammaticalized in a few modern languages involves the word for 'child,' which in Proto-Bantu presumably was comprised of the noun class marker **mʊ̀-* prefixed on a root **-ɟánà*. This word has reflexes in most modern Bantu languages and appears often as *mwána* (Gweno), *ngwána* (Tswana), or something similar. In some Bantu languages, this word has grammaticalized into a diminutive marker, such as *mʊ̌-* (Ngombe) or *mwa-* (Makhuwa), via the construction 'child = small' + NOUN.

Subgrouping of the Present-Day Bantu Languages

There is no accepted subclassification of the Bantu languages, at least none that can claim any historical validity (see Nurse, 1994–1995). It has proven extremely difficult to establish a stable internal structure of subgroups based on shared innovations, regular sound changes, lexicostatistics, or whatever. One persistent problem is the many apparent diffusion phenomena.

Somewhat frustratingly, while "smaller regional studies have sometimes been hailed as the appropriate stepping stones towards the reconstruction of PB . . . they are often disappointing since the reconstructed

intermediate proto-language all too often very closely resembles PB' (Schadeberg, 2003: 159). In fact, the only currently used classifications are largely or entirely referential ones, especially that originally devised by Malcolm Guthrie in the late 1940s (see Guthrie, 1967–1971).

Lexicostatistics has been widely used in Bantu historical studies. Unfortunately, the results from different sources are usually inconsistent with one another. The more languages are included, the more difficult the results are to interpret. The merits and demerits of lexicostatistics (or its older version, glottochronology) has been an ongoing saga in linguistics ever since it was first presented by Morris Swadesh in the late 1940s. Despite the troublesome and often unreliable results it yields, the method keeps being used due to its relative simplicity.

Historical Scenarios: 'the Bantu Expansion'

Even though our understanding of the historical subgrouping of the Bantu languages is not too impressive, we can nonetheless say a bit about the history and development of the Bantu languages, or more particularly their speakers.

There have been two main controversies regarding the history of the Bantu languages. The first concerns place of origin, while the second concerns their spread over what is now the Bantu area. The former issue has by now been settled, the latter has not.

During the late 1940s, Joseph Greenberg suggested a place of origin somewhere along the southern Cameroonian/Nigerian border (see Greenberg, 1972), which is what everybody seems to agree with today. An opposing theory was advanced by Malcolm Guthrie (1962), and soon also Roland Oliver (1966), who located the birthplace of the Bantu languages in the south of the present-day Democratic Republic of the Congo. They came to this conclusion based on the erroneous assumption that the origin of a language group is likely to be where there is the least amount of linguistic diversity. Nowadays, it is a standard assumption that it is in fact the other way around, which was the line of reasoning Greenberg had used when he made his proposal.

As for the dispersal of the Bantu languages, no generally accepted theory has yet surfaced. Clearly, they have dispersed over a large area, but the debate continues over the issue of how exactly this dispersal happened, and why.

Early authors depicted a rapid spread of people who invaded, conquered, and extinguished everything that came in their way (see Johnson, 1919–1922). This idea of a swift, conquering (and violent) mass of people eventually became known as 'the Bantu expansion,' and it figures prominently in the early European literature on the Bantu languages and their speakers. In modern times, most (if not all) efforts at reconstructing the historical scenario concerning the dispersal of the Bantu languages have combined various bits and pieces of archaeological, anthropological, and linguistic evidence.

In fact, the descriptions of 'the Bantu expansion' have changed over time. During the mid-1960s, Roland Oliver observed that the speakers "must have expanded very rapidly indeed in order to have achieved such a wide geographical dispersion along with such a small degree of linguistic divergence" (Oliver, 1966: 362). He saw the main cause for this in a massive population growth, fueled by a "food-producing revolution" (1966: 363), mainly through the introduction of grain crops, wheat and barley.

During the 1970s, another theory took over when David Phillipson suggested a correlation between the dispersal of the Bantu languages and the spread of Iron Age culture, as deduced from, in particular, various forms of ceramic artifacts. "Although general correlation between the spread of the Bantu languages and that of Iron Age culture in what is now Bantu Africa, is almost certainly an oversimplification, it seems to be holding up reasonably well" (Phillipson, 1976: 65).

Since the 1980s, Jan Vansina has set out to dispel what he sees as myths about 'the Bantu expansion.' He completely rejects the correlation between Iron Age culture and the Bantu languages. Instead, the spread of the Bantu speakers/languages happened long before the Iron Age. He depicts an original dispersal from present-day southern Cameroon/Nigeria to the areas around the Great Lakes in (noncoastal) east Africa. Eventually they came to occupy much of the rain forest area, from where the languages diversified into a western and an eastern group, slowly dispersing southwards. The entire process was a slow one, and it involved "many successive Bantu dispersals rather than a single continuous expansion" (Vansina, 1995: 190). The main cause of these dispersals was the growth of a farming culture. "Three dynamics must be considered here: the initial adoption of rudimentary farming, the intensification of farming during a long subsequent formative period until farming had become the main source of food and, finally, later innovations in mature farming systems" (Vansina, 1994–1995: 17) (see **Figure 1**).

All historical scenarios rely on a mixture of archaeological, anthropological, and linguistic evidence. The linguistic data used has varied from time to time. Roland Oliver relied on Malcolm Guthrie's ill-advised ideas about where the birthplace of the

Figure 1 Two possible historical scenarios for the dispersal of the Bantu languages. (A) Adapted from Heine *et al.* (1977). (B) Adapted and simplified from Vansina (1995).

Bantu languages might lie. David Phillipson relied on lexicostatistical calculations made by Heine *et al.* (1977), while Jan Vansina has relied on more up-to-date lexicostatistical studies made at Tervuren (see Bastin *et al.*, 1999).

Thus, to summarize, virtually all Bantuists today agree that Proto-Bantu was spoken some 3000 to 5000 years ago, somewhere in southern Nigeria/Cameroon. From there, the Bantu languages subsequently spread and diversified into the areas where they are found today. However, the explanations for this spread/dispersal/expansion are undecided on the issue of whether it was a caused by a food-producing revolution, knowledge of iron smelting, or a slowly growing farming culture.

Proto-Bantu Culture

In the early 1970s, Edgar Polomé (1975) analyzed the then available reconstructed Proto-Bantu vocabulary, and summarized what could be said about the original Proto-Bantu speakers and their culture. More recent sources, such as the BLR3 database, can further allow us to deduce (with some caution) much interesting information about Proto-Bantu culture. The Proto-Bantu examples given below are ones which have widespread reflexes in modern Bantu languages (though not, of course, in every single one).

The Proto-Bantu vocabulary points towards a savanna culture. Words for animals and insects abound, e.g., **-còkó* 'monkey sp.,' **-kímà* 'monkey sp.,' **-címbá* 'wild cat,' **-gòì* 'leopard,' **-kíá* 'antelope sp.,' **-pàda* 'impala,' **-cíndí* 'squirrel,' **-pʊ́kʊ̀* 'rat, mouse,' **-bébá* 'rat sp.,' **-kòcʊ́è* 'rat sp.,' **-pʊ́ngʊ́* 'eagle,' **-kʊ́àdí* 'francolin,' **-ɟíbà* 'pigeon,' **-ògù* 'elephant,' **-gùbʊ́* 'hippopotamus,' **-gàndʊ́* 'crocodile,' **-bʊ́dʊ́* 'monitor lizard,' **-cátò* 'python,' **-píḍɪ* 'puff adder,' **-búbì* 'spider,' **kʊ́ngá* 'eel,' and more.

They kept cattle (**-gòmbe* 'cattle', **-tàngá* 'cattle post'), goats (**-bʊ́dì*), pigs (**-gʊ̀dʊ́bè*), chicken (**-kókó*), and they hunted with javelins/spears (**-túmò*, **-gòngá*), as well as bow (**-táà*) and arrow (**-gúí*). They also built traps (**-támbò* 'trap, net,' **-tég* 'set trap') and caught fish (**-cúí* 'fish,' **-dób-* 'fish with line,' **-dóbò* 'fishhook').

Whoever spoke Proto-Bantu was familiar with agriculture (**-bìad-* 'plant, sow,' **-ḍ̀ ɪm-* 'cultivate (esp. with hoe)', **-cìd-*'grind'), including various food products such as cereals (**-bèdé* 'sorghum, millet'), beans (**-kʊ́ndè*), bananas (**-kòndè*), and much else. The fig tree (**-kʊ́ɟʊ̀*) is said to be the only known name for fruit trees.

Among their many useful tools, we can find axes and hoes (**-còká* 'ax,' **-témò* 'hoe, ax,' **-jʊ̀ndó* 'hammer, anvil, axe, iron'). Whether or not the Proto-Bantu knew iron smelting and/or used iron tools, as might be implied by a reconstruction like **-gèdà* 'iron, iron thing', seems to be an unresolved issue presently. Many of the suggested iron-related reconstructions can be derived from words with non-iron-related meanings, for instance, **-tádè* 'iron ore, iron, wire', which may derive from **-tádè* 'stone' (see Schadeberg, 2003: 159).

Their food was fried/roasted (**-káng*) or cooked/boiled (**-ɟìpɪk-*). They made and used baskets (**-tʊ́ndʊ́*), clay pottery (**-bʊ́mb-* 'mould pottery'), canoes (**ɟátò*), and many other useful things. They also made use of alcoholic beverages (**-dògù* 'wine, beer', **-kòdʊ* 'become intoxicated'), played music (**-gòmà* 'drum,' **-ḍ̀ ɪmbà* 'lamellophone'), and danced and sang (**-bín-*, **-ɟímb-*).

Final Words

The above text has aimed to familiarize the reader with some of the current state of affairs regarding Proto-Bantu studies. For advanced technical details and specific literature recommendations, the interested reader is suggested to read the most recent and

up-to-date handbook on the Bantu languages, aptly titled *The Bantu languages* (Nurse and Philippson, 2003a). Much of the information and some of the examples above derive from the many excellent contributions in there.

Proto-Indo–European Morphology

J H Jasanoff, Harvard University, Cambridge MA, USA

© 2006 Elsevier Ltd. All rights reserved.

General

Proto-Indo–European (PIE), like its earliest daughters (Hittite, Vedic Sanskrit, Avestan, Greek, Latin, etc.) was a highly inflected language. It is important to emphasize this fact in view of the many ways in which our view of PIE morphology has changed since the 1960s. For much of the 20th century, the burning questions in IE linguistics lay in the area of phonology, as scholars struggled to determine the number and character of the laryngeal consonants assignable to the protolanguage. It was only later, with the emergence of a consensus on laryngeals and the development of new methods of linguistic and philological analysis, that the 20th-century revolution in IE phonology began to spill over into morphology. Here the result was an even more radical rethinking of the traditional picture. The 'new look' of PIE morphology differs profoundly from the classical account by Brugmann (b. 1849) and newer works in the Brugmannian tradition. But attempts to portray PIE as a 'simpler' (i.e., less morphophonemically complex) language than its daughters have proved misguided.

The basic architecture of PIE was like that of any early IE language. The subject of a sentence stood in the nominative case and agreed with its verb in person and number; the verb was also marked for diathesis or 'voice' and for a variety of tense-aspect and modal categories. Nominal (i.e., substantival and adjectival) stems distinguished gender as well as case. An assortment of derivational processes allowed the formation of nominal and verbal stems from roots or simpler derived stems. Suffixation and ablaut, typically accompanied by movement of the accent, were the commonest devices for marking inflection and derivation. Prefixation as such was virtually unknown, but nouns and verbs combined freely with local particles (preverbs) in ways that tended to lead to the emergence of true prefixes in the daughter languages.

Although PIE distinguished sharply between nominal and verbal stems, a few generalizations can be stated for both. At the heart of every PIE noun or verb (pronouns are discussed separately) was a root. PIE roots were characteristically monosyllabic complexes of the form $*(s)C_1(C_2)EC_3(C_4)$-, where the symbols C_1, C_2, etc., stand for consonants and E stands for a variable vowel. All roots ended in a consonant; traditionally reconstructed preforms such as **dhē-* 'put' and **stā-* 'stand' are now known to have ended in a laryngeal (**dheh$_1$-*, **steh$_2$-*). Whether all roots also began with a consonant is less clear but often assumed. Certain consonant combinations (e.g., plain voiced stop + plain voiced stop; voiceless stop + voiced aspirate, in either order) were disallowed within a single root, a fact that may shed light on the prehistory of the PIE stop system. Some roots, such as **trem-* and **tres-*, both meaning 'tremble,' and **dreh$_2$-* or **drem-*, both meaning 'sleep,' seem originally to have contained an internal morpheme boundary. A boundary is obvious in cases such as **h$_2$u̯eks-* and **h$_2$eu̯g-* 'increase, grow,' where the final **-s-* is known to be an obsolete stem-formative.

Roots combined with one or more optional suffixes to form stems. PIE suffixes were of two canonical types, thematic and athematic. Thematic suffixes were of the form $*\text{-}(C_1)(C_2)(C_3)e/o$-, where the final element, called the thematic vowel, was realized as

*-*e*- or *-*o*- depending on the character of the following suffix or ending. Athematic suffixes were of the form *-(C_1)(C_2)(E)C_3(C_4)-; the more elaborate such morphemes resembled roots. Many suffixes, especially the longer thematic ones, can be analyzed into simpler constituents. Thus, for example, the instrumental suffix *-*tre/o*- clearly consists of a reduced form of the agent-noun marker *-*ter*- followed by the minimal thematic suffix *-*e/o*-.

Most roots and many athematic suffixes could appear in more than one ablaut grade. Ablauting roots and suffixes are conventionally cited in the *e*-grade (*$steh_2$-, *$h_2\underset{\smile}{u}eks$-, *-*ter*-, etc.; a small minority of roots had *-*a*- for *-*e*-). *e*-grade roots and suffixes alternated in principle with *o*-grade, zero-grade, and, less frequently, *ē*-grade and *ō*-grade (= lengthened-grade) versions of the same morphemes. All five possibilities can be seen in the suffixal second syllable of the Greek words for 'father': *e*-grade *-*ter*- in ACC SING *patér-a*; *o*-grade *-*tor*- in ACC SING *eu-pátor-a* 'having a noble father'; zero grade *-*tr*- (antevocalic) and *-*$t\underset{\circ}{r}$*- (anteconsonantal) in GEN SING *patr-ós* and DAT PL *patrá-si* (< *-*$t\underset{\circ}{r}si$), respectively; *ē*-grade *-*tēr*- in NOM SING *patēr*; and *ō*-grade *-*tōr*- in NOM SING *eu-pátōr*. As even these few examples suggest, ablaut was morphologically, not phonologically, regulated in PIE. Every athematic stem was associated with one of a limited number of ablaut/accent patterns that speakers learned when they acquired PIE as their native language. Ablauting stems had 'strong' and 'weak' variants, each proper to specific positions in the paradigm. In the case of the uncompounded word for 'father,' the strong stem was *ph_2-*tér*- (cf. Gk. ACC. SING. *patér-a*) and the weak stem was *ph_2-*tr'* (GEN SING *patr-ós*).

Thematic stems presented fewer complexities. Here, although the material preceding the thematic vowel might theoretically appear in any ablaut grade or combination of ablaut grades, there was no alternation within the paradigm. Thus, for example, the related PIE words *$\hat{g}\underset{\circ}{n}h_1$-*té/ó*-'born' and *$\hat{g}énh_1$-*te/o*- 'thing born, child' formed a minimal pair, the first with zero grade and the second with *e*-grade of the root *$\hat{g}enh_1$- 'be born.' But both words inflected in the same way, adding the case endings to the thematic vowel and maintaining the vocalism of the root syllable unchanged.

Other PIE morphological processes were reduplication and infixation, both almost wholly confined to the verb, and compounding, confined to the noun.

Nominals

Nominal Inflection

The categories of PIE declension were gender (masculine, feminine, and neuter), number (singular, dual, and plural), and case (nominative, accusative, genitive, dative, instrumental, ablative, locative, and vocative; there is in addition some evidence for an allative or directional). Not all the possible combinations of gender, number, and case corresponded to distinct forms. There were many recurrent syncretisms. The dative and ablative plural were always alike, so were the nominative and vocative plural; the nominative, accusative, and vocative dual; the dative, ablative, and instrumental dual; and the nominative and accusative of neuters in all three numbers. Neuters had the further oddity that the NOM-ACC PL form, as an old collective, took singular agreement (cf. Gk. *tà zṓa trékhei* 'the animals (NUNT PL) run,' with 3 SING *trékhei* for expected 3 PL *trékhousi*). Many stems, even when employed adjectivally, made no formal distinction between masculine and feminine, a fact that has been taken to suggest that the masculine : feminine contrast grew out of a pre-PIE 'animate' category.

Table 1 Reconstructed nominal endings

	Singular	*Plural*	*Dual*
NOM	*-*s* (*-*Ø*)[a]	*-*es*	*-h_1(*e*)
ACC	*-*m*	*-*ms*[b]	= NOM

VOC	*-*Ø*	= NOM	= NOM

[a]*-*s* was lost with compensatory lengthening in sequences of the type *-*VR-s* ('Szemerényi's Law').
[b]Exceptionally segmentable as acc.sg. *-*m* + *-*s*.
[c]*-*es* when accented, otherwise *-*s*.
[d]**H* = unknown laryngeal, probably *h_1 or *h_3.
[e]Uncertain.
[f]Like the other *bh*-endings (see notes *g*, *i*), only reconstructible for the IE phase following the separation of Anatolian (and Tocharian?) from the rest of the family. The earlier DAT PL ending may have been *-*os*.
[g]See note *f*. What followed the *-*bh*- is unclear.
[h]*-*éh*$_1$ when accented, otherwise *-h_1.
[i]See note. The earlier ending may have been *-*is*.
[j]*-*i* was a particle, optionally added to the properly endingless LOC. SG.

The nominal endings themselves were mostly portmanteau morphs, each one standing for a case + number combination without any clear segmentation into case and number components. The forms can be reconstructed as shown in Table 1.

How the declensional system worked in detail can be seen from the singular and plural forms of the nouns *$g^{\underset{\smile}{u}}$*ó*$\underset{\smile}{u}$-(strong stem; weak stem *$g^{\underset{\smile}{u}}$*é*$\underset{\smile}{u}$-) 'cow' (FEM) and (singular only) *$d\underset{\smile}{i}$*é*$\underset{\smile}{u}$- (strong stem; weak

[a]With analogical lengthening taken from *r*- and *n*-stem cases like *ph_2-tḗr < *-tér-s.
[b]Cf. Ved. *gā́m, dyā́m*. Phonologically regular from *g^{u}óm-m, *di̯ém-m < *g^{u}óu̯-m, *di̯éu̯-m.
[c]See note b; by inner-PIE sound change from *g^{u}óu̯-ms.
[d]Cf. Avestan *gaoš*.
[e]*-*ē*- theoretically expected but unattested.

stem *diu̯-) 'sky, Father Sky' (MASC), as shown in Table 2. The strong cases in PIE declension were the nominative, accusative, and vocative; everything else was weak. (The LOC SING, was based on a secondarily strengthened form of the weak stem.) The words for 'cow' and 'sky' were root nouns, formed without a derivational suffix. Such nouns could belong to one of several different ablaut types: in addition to the *o : *e type represented by *g^{u}óu̯-/*g^{u}éu̯- (cf. also *pód-/*péd-'foot,' *dóm-/*dém-'house,' etc.) and the *e : *zero type represented by *di̯éu̯-/*diu̯-′ (cf. also *léuk-/ *luk-′ 'light,' etc.), there is evidence for a type with stable *ē*-vocalism, seen, for example, in *h_3rḗĝ- 'king(let).'

Suffixed athematic nouns, including a large number in which the suffix was simply a frozen constituent of the stem with no remaining synchronic function, likewise displayed a variety of ablaut patterns. At least five underlying types can be distinguished:

- **Acrostatic I**, with fixed accent and *o : *e ablaut in the root syllable and fixed zero grade in the root syllable. Examples: *nók^{u}-t-s*, GEN *nék^{u}-t-s* 'night' (FEM); *dór-u-Ø*, GEN *dér-u-s* 'wood' (NEUT); *u̯ód-r̥-Ø*, GEN *u̯éd-n̥-s* 'water' (NEUT.; an '*r*/*n*-stem,' with *-*n*- substituting for *-*r* in the oblique cases).
- **Acrostatic II**, with fixed accent and *ē : *e ablaut in the root syllable and fixed zero grade in the root syllable. Examples: *mḗn-i-s*, GEN *mén-i-s* 'anger' (FEM); *sḗd-s-Ø*, GEN *séd-s-s* 'seat' (NEUT); *Hi̯ḗk^{u}-r̥-Ø*, GEN *Hi̯ék^{u}-n̥-s* 'liver' (NEUT).
- **Proterokinetic**, with accented *e*-grade root and zero-grade suffix in the strong stem, and zero-grade root and accented *e*-grade suffix in the weak stem. Examples: *mén-ti-s*, GEN *mn̥-téi-s* 'mind, thought' (FEM); *g^{u}ḗn < *g^{u}én-h_2*, GEN *g^{u}n-éh$_2$-s* 'woman' (FEM, but with *-Ø for *-*s* in the NOM SING); *$h_1$néh$_3$-mn̥-Ø*, GEN *h_1n̥h$_3$-mén-s* 'name' (NEUT). It was a peculiarity of this type that the non-neuter NOM PL was weak: *mn̥-téi̯-es* 'thoughts,' *g^{u}n-éh$_2$-es* 'women.'
- **Hysterokinetic**, with zero-grade root and accented *e*-grade suffix in the strong stem, and zero-grade root and zero-grade suffix in the weak stem, with accented endings. Examples: *ph_2-tḗr*, GEN *ph_2-tr-és* 'father' (MASC); *uks-ḗn*, GEN *uks-n-és* 'ox' (MASC); *si̯uH-mḗn*, GEN *si̯uH-mn-és* 'thread' (MASC).
- **Amphikinetic** (or holokinetic), with accented *e*-grade root and *o*-grade suffix in the strong stem, and zero-grade root and zero-grade suffix in the weak stem, with accented endings. Examples: *pént-oh$_2$-s*, GEN *pn̥t-h$_2$-és* 'path' (MASC); *dhéĝh-ōm*, GEN *dhĝh-(m̥)m-és* 'earth' (MASC); *u̯ék̂-ont-s*, GEN *uk̂-n̥t-és* 'willing' (MASC).

This classification is 'ideal' in the sense that the theoretically expected distribution of ablaut grades was susceptible to analogical leveling, sometimes within PIE itself. Thus, for example, the proterokinetic abstracts in *-*tei*- mostly generalized the zero grade of the root throughout the paradigm (cf. Ved. nom. *matís*, GEN *matés* 'thought,' Lat. *mēns, mentis*, Go. *-munds*, Lith. *mintìs*, pointing to regularized *mn̥-tí-/*mn̥-téi-); the neuter abstracts in *-*es*-, likewise originally proterokinetic, eliminated ablaut even more extensively (cf. Ved. NOM *jánas*, GEN. *jánasas* 'race', Gk. *génos, géneos*, Lat. *genus, generis*, pointing to stabilized *ĝénh$_1$-os*, GEN *ĝénh$_1$-es-es*). By the period of the individual daughter languages, the original system of ablaut/accent types had broken down into a system of *i*-stems, *u*-stems, *r*-stems, and so on, each corresponding to a distinct paradigm.

Thematic nouns, or '*o*-stems,' fused the case ending with the final vowel of the stem. In a few cases the ending itself was anomalous, probably borrowed from the declension of demonstrative pronouns. Table 3 lists typical the examples *h_1éḱ-u̯e/o-'horse' (MASC.) and *i̯ug-é /ó-'yoke' (NEUT) (the dual is omitted). Stems of this type, with their stable ablaut, fixed accent, and easy combinability with endings of every shape, became extremely productive in late PIE and the daughter languages.

Nominal Derivation

The parent language employed both external and internal derivational processes – the former modifying the derivational base by adding a suffix, the latter modifying the base by changing its ablaut/accent pattern. In practice, it is not always easy to tell the two apart. Thus, a suffix of the general form *-(*e*)*u*- made both acrostatic nouns of the type *krót-u-/*krét-u-

[a] **-ōs* = **-o-es*.
[b] With the collective ending **-h₂*.
[c] **-os* (i.e., **-o-s*), the original ending, is found in Hittite; the particle **-i̯o* was added later.
[d] **-ōi* = **-o-ei*.
[e] An apparently pronominal ending; segmentation unclear.
[f] The only place in the PIE nominal system where the ABL SG is distinct from the GENSG
[g] Trisyllabic.
[h] Or **-osu*?
[i] Uncertain.

'power' (= Ved. *krátu-*) and proterokinetic adjectives of the type **krét-u-/*kr̥t-éu-* 'strong' (= Ved. *kratú-*, Gk. *kratús*). The latter, from the point of view of the later IE languages and perhaps late PIE itself, was a *u*-stem adjective, representing a productive class characterized by proterokinetic **-eu-* (cf. **gʷérh₂-u-/*gʷr̥h₂-éu-*'heavy,' **h₁u̯ér-u-/*h₁ur-éu-* 'broad', etc.). In origin, however, **krét-u-/*kr̥t-éu-* was clearly an internal derivative of the noun **krót-u-/*krét-u-*, the change in form from acrostatic to proterokinetic inflection being associated with the change in meaning from 'power' to 'having power, strong.' Many similar cases are known, including, for example, the agent nouns in **-tér-/*-tr-'* (hysterokinetic) and **'-tor-/*-tr-'* (amphikinetic), based on proterokinetic action nouns in **'-tr̥ /*-tén-* (e.g., **déh₃-tr̥* (NOM SING) 'act of giving, gift' ⇒ **dh₃-tḗr*, **déh₃-tōr* 'giver' < *'having a gift' (= Gk. *dotḗr*, *dṓtōr*)); and the quasiagent nouns in **'-mon-/*-mn-'* (amphikinetic), based on proterokinetic action nouns in **'-mn̥-/*-mén-* (e.g., **séh₁-mn̥*⇒(NOM SING) 'sowing, seed' (= Lat. *sēmen* 'seed') ⇒ **séh₁-mō* <***-mōn* 'sower, seed god' < *'having seed' (= Lat. *Sēmō*)).

Internal derivation of this type had two other main functions in PIE – to form neuter collectives from neuter singulars (e.g., **u̯ód-r̥* (acrostatic NOM-ACC. SING 'water' ⇒ **u̯éd-ōr* <**-or-h₂* (amphikinetic NOM-ACC. 'plural') 'mass of water'), and to allow existing nominal stems to stand in second position in possessive ('bahuvrihi') compounds (e.g., **ph₂-tḗr* (hysterokinetic NOM SING) 'father' ⇒ **h₁su-p(é)h₂-tōr* (amphikinetic NOM SING) 'having a noble father.' There is reason to believe that these latter two functions were an outgrowth of the first ('X' ⇒ 'having X'). In all three cases the formal implementation was the same: acrostatic inflection was replaced by proterokinetic or amphikinetic, proterokinetic inflection was replaced by hysterokinetic or amphikinetic, and hysterokinetic inflection was replaced by amphikinetic. The amphikinetic type stood at the end of the derivational chain; amphikinetic stems had no formally distinct internal derivatives.

Partly because of the role of internal derivation, any attempt to itemize the PIE suffix inventory must be somewhat arbitrary. Even the shortest list of productive athematic suffixes, however, would include the following:

- *i*-stems. Abstract nouns (acrostatic) and adjectives (proterokinetic) in **-(e)i-*; abstract nouns (proterokinetic) in **-t(e)i-*.
- *u*-stems. Adjectives (proterokinetic) in **-(e)u-*; abstract nouns (proterokinetic) in **-t(e)u-*.
- *r/n*-stems. Abstract nouns and concretized action nouns (proterokinetic) with collectives (mostly amphikinetic) in **-u̯(e)r/n-*, **-s(e)r/n-*, **-t(e)r/n-*.
- *r*-stems. Agent nouns (hysterokinetic, amphikinetic) in **-t(e)r-*; derived feminines in **-s(e)r-*.
- *n*-stems. Individualizing and delocatival nouns and adjectives (hysterokinetic, amphikinetic) in **-(e)n-*; possessive adjectives (amphikinetic) in **-H(e)n-*; abstract nouns (proterokinetic) and adjectives, often substantivized (hysterokinetic, amphikinetic), in **-m(e)n-*.
- *nt*-stems. Possessive adjectives, often specialized as participles (mostly hysterokinetic, amphikinetic) in **-(e)nt-*; possessive adjectives (hysterokinetic, amphikinetic) in **-(e)nt-*; possessive adjectives (hysterokinetic, amphikinetic) in **-u̯(e)nt-*, **-m(e)nt-*.
- *s*-stems. Abstracts and concretized action nouns (proterokinetic) with possessive adjectives (hysterokinetic) and collectives (amphikinetic) in **-(e)s-*; comparative adjectives (amphikinetic) in **-i̯(e)s-*; perfect participles (amphikinetic) in **-u̯(e)s-*.
- *h₂*-stems. Abstracts, collectives, and feminine derivatives of thematic stems (apophonically invariant) in **-h₂-*; feminine derivatives of athematic stems (proterokinetic) in **-i̯(e)h₂-*.

Thematic stems present complexities of their own. An echo of internal derivation can be detected in the contrast between **tóm-e/o-* (Gk. *tómos*) 'act of cutting, a cut' and **tom-é/ó-* (Gk. *tomós*) 'cutting, inflicting cuts,' with suffixal **-e/o-* paralleling the **-(e)u-* of the derivational series **krót-u-/*krét-u-/*kr̥t-éu-*. A separate suffix **-e/o-* formed adjectives of appurtenance, as in **dei̯u̯-é/ó-* 'belonging to the sky, god' (: **di̯u̯-*'sky'), with the ablaut strengthening of the root known as *vr̥ddhi*. Longer PIE thematic

Table 4 Demonstrative suppletive paradigm

	Singular			*Plural*		
	Masc.	*Fem.*	*Neut.*	*Masc.*	*Fem.*	*Neut.*
NOM	**so*	**seh₂*	**tód*	**tói*	**téh₂es*	**téh₂ (*tói)*[a]
ACC	**tóm*	**téh₂m*	**tód*	**tóms*	**téh₂(m)s*[b]	**téh₂ (*tói)*[a]
GEN	**tósi̯o*	**tési̯eh₂s*	**tósi̯o*	**tóisoHom*	**téh₂soHom*	**tóisoHom*
DAT	**tósmōi*	**tési̯eh₂ei*	**tósmōi*	**tóibh(i̯)os*	**téh₂bh(i̯)os*	**tóibh(i̯)os*

[a] **tói* was the PIE form, remade to **téh₂* (''**tā́*'') after the separation of Anatolian from the rest of the family.
[b] With loss of the **-m-* by inner-IE sound change.

suffixes, all probably composite in origin, included **-i̯e/o* (adjectives of appurtenance, e.g., **h₁éḱu̯-i̯e/o-* 'equine'), **-re/o-* (possessive adjectives based on root nouns, e.g., **h₁rudh-ré/ó-* 'having redness, red'), **-ne/o-* (verbal adjectives and adjectives of appurtenance, e.g., **pl̥h₁-né/ó-* 'full'), and many others. The highly productive suffix **-te/o-*, in isolation a source of verbal adjectives and participles (e.g., **ḱlu-té/ó-* 'heard, famous'), combined with the comparative suffix **-i̯(e)s-* to yield **-is-te/o-*, used to form superlative adjectives. Every older IE language except Hittite presents a characteristic proliferation of thematic suffixes, each with its regularly formed feminine in **-ā-* (i.e., **-e-h₂-*).

Pronouns and Other Declinables

The PIE personal pronouns were highly idiosyncratic. Unlike nouns, in which the major formal division in the paradigm separated the nominative and accusative from the weak cases, the basic split in the paradigm of the personal pronouns came between the nominative and the other case forms. Thus, the first-person singular pronoun was **(h₁)eĝóh₂* or **(h₁)eĝh₂óm* in the nominative but **méh₁/*me* (ACC), *ménе/*moi* (GEN), and **méĝhi/*moi* (DAT) in the other forms (cf. Eng. *I* vs. *me, my*). The situation was similar in the first-person plural (NOM **u̯éis* vs. OBL **nos-*, **n̥s-*; cf. Eng. *we* vs. *us*) and second-person plural (NOM **i̯úHs* vs. OBL **u̯os-*, **us-*), and only slightly less anomalous in the second-person singular (NOM **túH* vs. OBL vs. OBL **te-*, **tu̯e-*). The second-person singular forms were paralleled outside the nominative by the forms of the reflexive pronoun **s(u̯)e-*.

In lieu of proper third-person pronouns, PIE employed the demonstrative elements **(h₁)e/o-*, **(h₁)ei-*, **se/o-*, and **te/o-*. Of these, the last two were associated in a single suppletive paradigm, part of which can be reconstructed as shown in Table 4. The formal separateness of the animate NOM SING forms, recalling the separate nominative of the personal pronouns, is an obvious archaism. Other visible marks of the pronominal declension were the NOM-ACC neuter ending **-d*, the appearance of 'stem extenders' such as **-smo-* in the DAT SING and **-s-* in the GEN PL, and the appearance of a 'plural stem' in **-oi-* running through most of the most of the masculine and neuter plural forms. These features recurred in the inflection of the interrogative and indefinite **kᵘé/ó-/*kᵘí-*, the relative **Hi̯é/ó-*, and bimorphemic formations of the type **kᵘó-tere/o-* 'which of two' and **(h₁)é-ne/o-* 'that one there.'

The complexities of PIE nominal stem formation and declension can be seen in microcosm in the cardinal numerals. Of these, 'one' through 'four' were fully inflected adjectives of a variety of formal types, where as most of the remaining numerals through '10' were indeclinable adjectives ('eight' was a thematic dual). The decades and hundreds were nouns, all ultimately based on the internal and external derivatives of the underlying stem **déḱm̥t-*'decade' (cf. **u̯úh₁-(d)ḱm̥t-ih₁* '20' (= 'two decades'), **tríh₂-(d)ḱomt-h₂* '30' (= 'three decades'), **(d)ḱm̥t-ó-m* '100' (= 'tenth (decade),' etc.).

Verbs

Verbal Inflection

The PIE verb was inflected in the singular, dual, and plural for categories of tense and aspect, voice, and mood. The most basic tense/aspect contrast was that between the present stem, with imperfective aspectual value, and the aorist stem, with perfective value. Many, although by no means all, verbal roots formed stems of both types. From the present stem were formed two tenses – a present tense in the narrow sense, which represented the verbal action (or process or state) as taking place in actual or general present time, and an imperfect tense, which represented the action as taking place in the past. The aorist stem, prevented by its perfective meaning from being used with the sense of an actual ('here and now') present, formed the basis of the aorist tense, which usually functioned as a perfective preterite. A third type of stem, the perfect stem, underlay the perfect tense and its past-time counterpart, the pluperfect. In origin,

	3	**gʷhn-énti*	**gʷhn-ént*	**dhugh-rór*	**dhugh-ró*

however, the perfect was a type of present, the specific function of which was to denote the state resulting from the completion of a process (e.g., 3 SING PERF **memón-e* 'has in mind' vs. 3 SING AOR **mén-to* 'brought to mind'). The evolution of the perfect from a pure stative to a resultative preterite along the lines of Eng. *I have seen* was in part a post-PIE development.

There were two voices or diatheses, traditionally called active and middle (or mediopassive) and marked by separate sets of personal endings. The two were not always opposed; many roots and stems had only active or only middle forms. When they did contrast, the middle signaled the involvement of the subject in the verbal action, either by giving it an intransitive, reflexive, or processual reading or by introducing a semantic element of self-interest (cf. Ved. *yájate* (MID) 'sacrifices for oneself' vs. *yájati* (ACT) 'sacrifices for someone else'). There was no passive as such, although a passive often evolved from the middle in the daughter languages.

Apart from the indicative mood, PIE had a subjunctive, an optative, and an imperative. The subjunctive and optative both marked an action as unrealized, the subjunctive with a hint of wish or expectation, the optative with a note of doubt or contingency. The two were formed similarly – each inserted a mood sign between the stem and endings – and their distribution was partly complementary, the optative serving as a kind of preterite to the subjunctive. The imperative had no mood sign, but employed special endings.

The majority of finite verbal forms were made with either the active endings or the middle endings. Both sets had 'primary' and 'secondary' variants – the former used in categories with present time value (hence, preeminently the present indicative); the latter used elsewhere. The endings themselves had the forms shown in Table 5. The primary endings were for the most part built from their secondary counterparts by adding a further element – the deictic particle **i* in the most salient active forms and the deictic particle **r* in the middle. The difference between the two pairs of middle endings in the third person was originally chronological: **-o(r)* and **-(ē)ro(r)* are older than **-to(r)* and **-nto(r)*, which arose under the influence of the corresponding active forms. In the synchrony of late PIE, the choice of the one set or the other was partly determined by stem type. When the two sets contrasted, the forms in **-o(r)*/**-(ē)ro(r)* had intransitive value, whereas those in **-to(r)*/**-nto(r)* were usually transitive and self-benefactive (cf. Ved. *gr̥ṇā́ti* < **-ti* 'praises,' *gr̥ṇīté* < **-tói* (**-tór*) 'praises (from self-interest),' *gr̥ṇé* < **-ói* (**-ór*) 'is praised').

The mechanics of conjugation are illustrated in Table 6 with the present and imperfect active of **gʷhén-* (strong stem; weak stem **gʷhn-*') 'strike, slay' and the present and imperfect middle of **dhugh-*' (apophonically invariant) 'yield, produce' (the dual is omitted). The 'strong' positions in the verbal paradigm were the three persons of the active, sometimes joined, depending on specific category and stem type, by other forms. Middles showed no inner-paradigmatic ablaut but were formed from the weak stem of the corresponding active when such an active existed. The poorly attested third person singular middle corresponding to **gʷhén-ti* 'slays' was thus **gʷhn-ór* 'is slain'; the third-person singular active corresponding to **dhugh-ór*, if there had been one, would have been **dhéugh-ti*.

By late PIE times, the imperfect and other preterital tenses were preceded in narrative contexts by a particle known as the augment, probably originally a sentence-connective conjunction (**é-gʷhen-m̥* 'I slew' < *'and then I slew,' etc.). The augment, when present, combined more closely with the verb than adverbial preverbs of the type **pró* 'forth' and **ní* 'down', which were still separate words (cf. **ní* (...) *gʷhen-mi* 'I strike down,' **pró* (...) *dhugh-or* 'gives forth,' etc.). Univerbation of the verb with a preceding element was a persistent trend in the IE family, being favored by the fact that finite verbs were enclitic in main clauses.

The mood sign of the optative was an athematic suffix **-i̯éh₁-* / **-ih₁-*, which was added to the weak stem of the corresponding indicative and followed by the secondary endings (cf. 3 SING **gʷhn̥-i̯éh₁-t*, PL **gʷhn-ih₁-ént*; 3 SING **dhugh-ih₁-ó*, PL **dhugh-ih₁-ró*). The subjunctive marker was a suffix **-e/o-*, identical to the thematic vowel; it was added to the *e*-grade form of the stem and accompanied by the primary thematic endings (3 SING **dhéugh-e-tor*, PL **dhéugh-o-ntor*). In the imperative the second person plural and dual forms used the secondary endings (2 PL **gʷhén-te*, **dhugh-dh(u)u̯é*), but the second person singular had special endings – **-dhi* or zero in the active (**gʷhn̥-dhí*, **gʷhén*) and perhaps **-o* in the middle (**dhugh-ó?*). The third person imperative added a particle to the corresponding secondary endings, probably **-u* in the active and **-om* in the middle (**gʷhén-t-u*, **gʷhn-ént-u*; **dhugh-ōm*, **-rōm* < **-o-om*).

gʷhén-/ *gʷhn-'* and **dhugh-'* were root presents. Root presents of the alternative 'Narten' type showed **ē* : **e* ablaut and fixed accent on the root (3 SING **stḗu-ti* 'praises,' PL **stéu̯-n̥ti*), with accented *e*-grade rather than zero grade in the middle (3 SING **stéu̯-or*, etc.). There were also root aorists, formally similar to the imperfects of root presents. The majority of present and aorist stems, however, were characterized by an overt formative – a suffix, an infix, or reduplication. Interestingly, none of the inherited suffixes that served as tense/aspect markers in PIE displayed paradigmatic ablaut. Most PIE verbal suffixes were thematic (-e/o-*, **-i̯e/o-*, **sk̂e/o-*, **-ei̯e/o-*, etc.) and hence ablaut-free. The commonest athematic suffix was **-s-*, which formed both '*s*-presents' and '*s*-aorists'; characteristically, these showed ablaut of the root syllable (cf., e.g., 3 SING AOR **prḗk̂-s-t* 'asked,' MID **prék̂-s-to*) but not of the **-s-* itself. The unique example of a tense/aspect marker that **did** display ablaut was the nasal infix **-n(é)-*, which figured in presents of the type **i̯u-né-g-ti*: **i̯u-n-g-énti* 'yoke, join' (: **i̯eug-*) and **k̂l̥-né-u-ti* : **k̂l̥-n-u̯-énti* 'hear' (: **k̂leu-*); from **k̂l̥-n(é)u-* was extracted the quasi-suffix **-n(é)u-*, which played a descriptively important role in late PIE. Reduplicated formations included the athematic present type represented by **dhé-dheh₁-ti* (**-dhoh₁-?*): **dhé-dhh₁-nti* 'put, make' (: **dheh₁-*) and **dé-deh₃-ti* (**-doh₃-?*): **dé-dh₃-nti* 'give' (:**deh₃-*).

Table 7 Perfect and pluperfect

Perfect		*Pluperfect*	
Singular	*Plural*	*Singular*	*Plural*
1 **me-món-h₂e*	**me-mn̥-méH(?)*	**me-món-m̥*	**me-mn̥-mé(*-mén-?)*
2 **me-món-th₂e*	**me-mn-ó(?)*	**me-món–s*	**me-mn̥-té (*-mén-?)*
3 **me-món-e*	**me-mn-ḗr (*-ŕ̥)*	**me-món-t*	**me-mén-r̥s*

In addition to presents and aorists of these types, the PIE verbal system included forms that patterned functionally as actives but inflected with endings related to those of the middle. Here belonged in the first instance the perfect, originally a kind of reduplicated present with **o*: *zero* (for older **o* : **e*) ablaut, but already a formally and functionally distinct category in late PIE. The perfect and pluperfect active of the root **men-* 'bring to mind' presented a mixture of familiar and unfamiliar-looking forms, as shown in Table 7. Almost all perfects were conjugated like **me-món-/ *me-mn̥-'*, including the irregularly unreduplicated **u̯óid-/ *u̯id-'* 'know' (: **u̯eid-* 'see, catch sight of'). Internal reconstruction suggests that the pre-PIE ancestor of the perfect was a kind of middle, with an ancestral version of the middle endings. As the parent language evolved and the perfect ceased to be synchronically identified as a middle, its endings escaped the formal innovations (replacement of 3 SING **-e* by **-o*, replacement of 3 PL-**ḗr/ *-r̥* by **-(ē)ró*, etc.) that affected those of the middle proper. The perfect endings thus became, in effect, positional variants of the active endings. When the need arose for a set of 'secondary' perfect endings to mark the pluperfect, the active secondary endings were quite naturally exploited for this purpose (**memón-m̥*, **-s*, **-t*, etc.).

The perfect was not the only category that employed endings of the *h₂-e* series in an active function. Present formations that used perfect like endings included root presents with **o* : **e* ablaut (e.g., **mólh₂-* 'grind'), reduplicated presents with *i*-reduplication (e.g., **pí-bh₃-* (< **-ph₃-*) 'drink'), and denominative factitive presents in **-h₂-* (e.g., **néu̯e-h₂*-'make new'). There were also *h₂e*-conjugation root aorists, which, like the corresponding root presents, had **o* : **e* ablaut (e.g., **lógh-/ *légh-* 'lie down'). As a rule, the *h₂e*-conjugation mode of inflection remained clearly recognizable only in Anatolian. Apart from the perfect, the only direct trace of active

h_2e-inflection that survived into the non-Anatolian branches of the family was the first-person singular primary thematic ending **-o-h_2* (> Lat. -*ō*, GK. -*ō*, etc.), representing older **-o-h_2e*. Table 8 shows the present and imperfect active of the stem **bhér-e/o*-'bear.'

The appearance of **-o-h_2* for the expected **-o-mi* was thus a significant archaism. The thematic modal forms – in particular, the optative in **-oih_1-* (i.e., **-o-* + **-ih_1-*) and (apart from the 1 SING) the thematic subjunctive in **-ē/ō-* (i.e., **-e/o-* + **-e/o-*) – took the normal active and middle endings.

Most of the nominal forms of the PIE verb – active participles in **-(e)nt-*(NOM SING MASC **g^{u}hn-ónt-s*, **stéu̯-n̥t-s*, **bhér-o-nt-s*), perfect participles in **-u̯(e)s-*(NOM SING MASC **u̯eid-u̯ós*), and verbal adjectives (passive participles) in **-té/ó-* (NOM SING MASC **k̂lu-tó-s*) – have already been briefly mentioned. Middle participles, formed to present, aorist, and perfect stems alike, were marked by the phonotactically aberrant suffix **-m$h_1$ne/o-* (NOM SING MASC **dhugh-m̥$h_1$nó-s*, **bhér-o-m$h_3$no-s*, etc.). There was no well-developed system of infinitives; with the exception of a single inherited type based on the suffix **-dhi̯e/o-*, the forms that function as infinitives in the IE daughter languages are case forms of verbal nouns that became true infinitives in the dialectal period.

Verbal Derivation

The derivational morphology of the PIE verb was less complex than that of the noun. The basic organizational unit, as is still the case in Sanskrit, was the root. From the root were formed, first, a nucleus of one or more present and/or aorist stems that expressed the lexical meaning of the verb and, second, a more peripheral set of derivatives – desideratives, iteratives, causatives, and so on – that modified the lexical meaning in predictable ways. Not all roots, as already noted, formed both a present and an aorist. Many roots that made a root present lacked an aorist; this was the case, for example, with basic lexical items such as **$h_1$es-*'be,' **$h_1$ei-*'go,' **k̂ei-*'lie,' **u̯es-* 'wear,' **bher-* 'bear,' aoristic counterparts of which were supplied by other roots (**bhuH-* 'become,' **g^{u}em-* 'go,' etc.). Roots that made a root aorist, on the other hand, normally formed a present as well. In such cases the present was usually 'characterized,' either by a nasal infix (e.g., 3 SING AOR **i̯éug-t* 'yoked,' **k̂léu-t* 'heard': 3 SING PRES **i̯u-né-g-ti*, **k̂l̥-né-u-ti*; the commonest pattern), by reduplication (AOR **dhéh_1-t* 'put, made,' **stéh_2-t* 'stood (up)' : PRES **dhé-dheh_1-ti*, **stí-sth_2-e*), by the suffix **-i̯e/o-* (AOR **mén-to* 'recalled,' **bhóudh-e* 'awoke' : PRES **mn̥-i̯é-tor*, **bhudh-i̯é-tor*), or by any of a number of other suffixes (**-sk̂e/o-*, **-i-*, **-u-*, etc.). Evidence for a simple kind of internal derivation is provided by pairs of the type PRES **legh-ór* 'lies (down)' beside AOR **lógh-e*.

In addition to the root aorist, the other conspicuous aorist formation was the 'sigmatic,' or *s*-aorist. In its classical form, with **ē* : **e* ablaut and a fully sigmatic active and middle, the *s*-aorist was actually an early post-PIE creation; it never developed fully in Anatolian and Tocharian. But in the branches where the *s*-aorist established itself, it became enormously productive, serving, *inter alia*, as the aorist of choice for roots that made simple thematic presents (e.g., PRES **u̯éĝh-e-ti* 'conveys,' **dhég^{u}h-e-ti* 'burns' : AOR **u̯éĝh-s-t*, **dhḗg^{u}h-s-t*) and supplying aorists to derived presents that originally had no aorist at all.

The outer tier of the PIE verbal system consisted of the desiderative, iterative, causative, and other specially nuanced presents built to verbal roots and of denominative presents built to preexisting nominal stems. The most important suffixes underlying these formations were the following:

- **-éi̯e/o-*. Iteratives and causatives with *o*-grade of the root (e.g., **k̂lou̯-éi̯e/o-*'proclaim, cause to be heard').
- **-sk̂é/ó-*. Iteratives, inchoatives, and (secondarily) causatives, with zero grade of the root (e.g., **h_1s-sk̂é/ó* - 'be (habitually)').
- **-s-*(**-h_1s-* after liquids and nasals), **-s-e/o-*, **-s-i̯e/o-*. Desideratives, tending to evolve into futures in the daughter languages (e.g., **sḗd-s-* 'wish to sit').
- **-i̯é/ó-*(**-i-i̯é/ó-*, **-e-i̯é/ó-*, **-eh_2-i̯é/ó-* ('**-āi̯é/ó-*'), **-eh_1-i̯é/ó-* ('**-ēi̯é/ó-*'), etc.). Denominatives with the meaning 'be/become/wish to be/act like X' (e.g., **uksn̥-i̯é/ó-* 'act like a bull, be strong').
- **(-e)-h_2-*. Denominatives with the meaning 'make X,' built exclusively to thematic stems (e.g., **néu̯e-h_2-* 'make new').

A characteristic of such secondary stems was that they were exclusively presents; there were no desiderative, iterative, or denominative aorists and only the barest beginnings of a causative aorist based on the PIE reduplicated aorist (type **u̯é-uk^{u}-e-t* 'said'). Each branch of the family thus had to work out its own solution to the problem of how to provide its secondary presents with extrapresential tense forms.

Table 8 Perfect and imperfect

Present		*Imperfect*

Proto-Indo–European Phonology

B Fortson IV, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

The first attempts at reconstructing the Proto-Indo–European sound system took place in the mid-19th century. A rapid series of discoveries that culminated in the crystallization of Neogrammarian methodology in the 1870s and 1880s not only revolutionized the understanding of the language family but also ushered in true scientific study of language change. These discoveries allowed Indo–Europeanists gradually to free themselves from the belief that PIE was little different from Sanskrit, long held to be the most archaic and most perfect Indo–European (IE) language. By the close of the 19th century, the picture of PIE phonology that had been achieved was similar to what is generally accepted nowadays.

The subject of PIE phonology is as vast as the following survey is brief. In the interest of presenting as many of the basic facts as possible, the discussion of individual reconstructions has been kept to a minimum and the complete bodies of evidence for them can only be alluded to here and there. Although most of the claims in this article are not controversial, our picture of PIE is not set in stone and there are various competing minority views. Fuller elaborations of them and related issues may be found in the specialized sources listed in the bibliography.

Consonants

The PIE consonant inventory consisted mostly of stops, of which there were 15, distributed among five places of articulation (bilabial, dental or alveolar, palatal, velar, and labiovelar) that each had voiceless, voiced, and voiced aspirated varieties. In addition, the language possessed the nasals *m* and *n*, the liquids *l* and *r*, the sibilant fricative *s*, the glides *y* and *w* (more often written *i̯* and *u̯*), and three so-called 'laryngeals' of disputed phonetic character (see later discussion).

Stops

The stop inventory is shown in **Table 1**, using traditional notation. (Commonly used alternate notations are *ḱ, ǵ, ǵh* for the palatals; $k^{\underset{\smile}{u}}$, $g^{\underset{\smile}{u}}$, $g^{\underset{\smile}{u}}h$ for the labiovelars; and b^h, d^h, etc., for the voiced aspirates.) The voiced aspirates, still preserved as a class in most Indo–Aryan languages, are thought to have been voiced stops with murmur or breathy voice. A fourth series of stops, voiceless aspirated *ph*, *th*, *kh*, and so on was posited in earlier scholarship to account for correspondences such as Skt. and Gk. perfect indicative active second-person singular *-tha*; these are now generally regarded as post-PIE developments, although attempts to resuscitate this series for PIE still appear from time to time (e.g., Elbourne, 1998).

Space does not suffice for listing all the correspondence sets on which these reconstructions are based, but a few sample sets (themselves not exhaustive) are given here for illustration:

- For **p*, descendants of PIE **ped-* or **pod-* 'foot' (Luvian *pāta-*, Skt. *pad-*, Gk. *pod-*, Lat. *ped-*, Eng. *foot*, Tocharian A *pe*).
- For $*k^w$, descendants of $*k^wi$- or $*k^wo$- 'who' (Hitt. *kuiš*, Skt. *kás*, Gk. *tís* [dialectal *pís*], Lat. *quis*, OE *hwā*, Lith. *kàs*).

Table 1 PIE stop inventory

	Labial	*Dental*	*Palatal*	*Velar*	*Labiovelar*
Voiceles	p	t	*ḱ*	k	k^w
Voiced	b	d	ǵ	g	g^w

Proto-Indo–European Phonology

B Fortson IV, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

The first attempts at reconstructing the Proto-Indo–European sound system took place in the mid-19th century. A rapid series of discoveries that culminated in the crystallization of Neogrammarian methodology in the 1870s and 1880s not only revolutionized the understanding of the language family but also ushered in true scientific study of language change. These discoveries allowed Indo–Europeanists gradually to free themselves from the belief that PIE was little different from Sanskrit, long held to be the most archaic and most perfect Indo–European (IE) language. By the close of the 19th century, the picture of PIE phonology that had been achieved was similar to what is generally accepted nowadays.

The subject of PIE phonology is as vast as the following survey is brief. In the interest of presenting as many of the basic facts as possible, the discussion of individual reconstructions has been kept to a minimum and the complete bodies of evidence for them can only be alluded to here and there. Although most of the claims in this article are not controversial, our picture of PIE is not set in stone and there are various competing minority views. Fuller elaborations of them and related issues may be found in the specialized sources listed in the bibliography.

Consonants

The PIE consonant inventory consisted mostly of stops, of which there were 15, distributed among five places of articulation (bilabial, dental or alveolar, palatal, velar, and labiovelar) that each had voiceless, voiced, and voiced aspirated varieties. In addition, the language possessed the nasals *m* and *n*, the liquids *l* and *r*, the sibilant fricative *s*, the glides *y* and *w* (more often written *i̯* and *u̯*), and three so-called 'laryngeals' of disputed phonetic character (see later discussion).

Stops

The stop inventory is shown in Table 1, using traditional notation. (Commonly used alternate notations are *ḱ, ǵ, ǵh* for the palatals; $k^{\underset{\smile}{u}}$, $g^{\underset{\smile}{u}}$, $g^{\underset{\smile}{u}}h$ for the labiovelars; and b^h, d^h, etc., for the voiced aspirates.) The voiced aspirates, still preserved as a class in most Indo–Aryan languages, are thought to have been voiced stops with murmur or breathy voice. A fourth series of stops, voiceless aspirated *ph*, *th*, *kh*, and so on was posited in earlier scholarship to account for correspondences such as Skt. and Gk. perfect indicative active second-person singular *-tha*; these are now generally regarded as post-PIE developments, although attempts to resuscitate this series for PIE still appear from time to time (e.g., Elbourne, 1998).

Space does not suffice for listing all the correspondence sets on which these reconstructions are based, but a few sample sets (themselves not exhaustive) are given here for illustration:

- For **p*, descendants of PIE **ped-* or **pod-* 'foot' (Luvian *pāta-*, Skt. *pad-*, Gk. *pod-*, Lat. *ped-*, Eng. *foot*, Tocharian A *pe*).
- For $*k^w$, descendants of $*k^wi$- or $*k^wo$- 'who' (Hitt. *kuiš*, Skt. *kás*, Gk. *tís* [dialectal *pís*], Lat. *quis*, OE *hwā*, Lith. *kàs*).

Table 1 PIE stop inventory

	Labial	*Dental*	*Palatal*	*Velar*	*Labiovelar*
Voiceles	p	t	*ḱ*	k	k^w
Voiced	b	d	ǵ	g	g^w
Voiced aspirated	bh	dh	ǵh	gh	g^wh

- For the palatal velar *ĝ, descendants of *ĝonu, *ĝenu 'knee' (Hitt. *gēnu*, Skt. *jā́nu*, Gk. *gónu,* Lat. *genū*, Arm. *cownr*, OE *cnēo*).
- For the voiced aspirate *bh, the well-represented root *bher- 'bear, carry' (Skt. *bhárāmi*, Gk. *phérō*, Lat. *ferō*, OIr. *biru*, OE *bere*, all meaning 'I carry'; OCS *berǫ* 'I take').

In most branches, the voiceless and plain voiced stops remained intact (an important exception is Germanic, where they became, respectively, voiceless fricatives and voiceless stops by the sound change known as Grimm's law; note ***f**oot* and OE ***c**nēo* in the preceding paragraph). The voiced aspirates lost their aspiration in most branches, but in Greek they lost their voicing (as in Gk. *phérō*, phonetically [pʰɛrɔː]), and in Italic they often became fricatives (as in Lat. ***f**erō*).

The Velars and the 'Centum/Satem' Distinction The palatals, velars, and labiovelars are generally referred to collectively as 'velars' (also 'dorsals or 'tectals'). Whether the palatals were genuine palatal stops or simply palatalized velars as in Eng. *kin, keep*, Russ. *russkij* is not entirely clear. It is possible that the palatals and plain velars were once allophonic variants of one another, given that the plain velars are particularly commonly represented before the back vowel *a*. However, we cannot make do with only two phonemic series of velars for the stage of PIE directly preceding its breakup. First, there are three separate velar correspondences in practically identical phonetic environments in such cognate sets as shown in Table 2. Second, it was demonstrated (Melchert, 1987) that the Anatolian language Luvian contains three separate reflexes of the three series (***k**išammi-* 'combed' < ****k**es-*, *z**i**ya-* 'lie' < ****k̂**e̯i̯-o-* (*z* = [ts], ***k**uiš* 'who' < ****k**ʷis*). Several other branches, especially Albanian, have also been argued to preserve three reflexes in certain environments (for an overview, see Tischler, 1990).

But in general, outside Luvian, the three velar series have merged to two, or, in the case of Tocharian, only one. (The situation in Tocharian is actually more complicated in that there is a goodly residue of forms containing inherited labiovelars that show evidence of labialization, meaning probably that the labiovelars remained distinct from the other two series at least in some dialects.) In some branches (Greek, Italic, Celtic, Germanic, Tocharian), the palatals merged with the plain velars, whereas elsewhere (Indo–Iranian, Armenian, Balto–Slavic, and perhaps Albanian) it was the labiovelars that merged with the plain velars, leaving the palatals distinct (the latter developing subsequently into sibilants or affricates). Branches undergoing the first of these developments are termed 'centum' branches, whereas those undergoing the second are called 'satem,' after the Latin and Avestan words for 'hundred' (*centum* and *satəm*, respectively, where the initial consonant is from PIE *k̂-).

Table 2 Velar correspondences

Greek	*Sanskrit*	*Gloss*
kré(w)as	**k**rávis-	'gore'
klé(w)os	**ś**rávas	'fame'
príatai	**k**rīṇā́ti	'buys'

It is unclear whether the centum/satem distinction is simply a useful descriptive shorthand for what were (often parallel) independent developments in different branches, or represents a genuine deep dialectal division within IE. The latter view found support in the geographical distribution of the branches that were known to the first several generations of Indo–Europeanists: all the centum branches were located as a group, generally west of the satem languages. The discovery of Tocharian and Anatolian in the 20th century has rendered the issue much more controversial. Aside from the obvious complications introduced by the Luvian facts already discussed, the location of the probably centum Tocharian is problematic because it is farther east than any other branch. A further problem is posed by Balto–Slavic, which, although nominally satem, has numerous centum reflexes as well. Because of these difficulties, some scholars feel that the centum/satem distinction is meaningless for IE dialectology. But there are ways of salvaging the traditional hypothesis, and the issue remains unsettled.

The Glottalic Theory The stop inventory in the standard model has had detractors. The most well-known alternate view is the so-called glottalic theory, developed independently by the then-Soviet duo Tamaz Gamkrelidze and Vyacheslav Ivanov and by the American linguist Paul Hopper (see Hopper, 1973; Gamkrelidze and Ivanov, 1984). These researchers and their followers have sought to reinterpret the plain voiced stops as glottalized voiceless stops. This reinterpretation supposedly has the advantages of producing a typologically more natural stop inventory, of accounting for the co-occurrence restriction in IE roots whereby no root may contain two plain voiced stops, and of accounting for the near-absence of roots containing *b (= *p' in their system; this is the one consonant most commonly missing from glottalic inventories). But in spite of a not insignificant following for a time, the glottalic theory has not won widespread acceptance. There is no direct comparative evidence for glottalized consonants in reconstructible

PIE (although this, of course, does not preclude an earlier stage from having had them), which also means that positing them needlessly complicates the subsequent phonological histories of most of the branches. A few languages have recently been shown to have sound systems typologically similar to PIE's (e.g., Javanese, Madurese (Madura), and the Bario dialect of Kelabit in Sarawak), so the claim that PIE was typologically unnatural can now be seriously questioned. Finally, the consonant **b* was not absent from PIE, but merely rare, which tells us nothing definite about its anterior history.

Resonants and **s*

The nasals *m* and *n* and liquids *l* and *r*, collectively termed 'resonants' in IE studies, shared the ability to form syllabic allophones (notated *m̥ n̥ l̥ r̥*) when occurring between two nonsyllabics (e.g., **tn̥tos* 'stretched,' **u̯l̥kʷos* 'wolf') or between nonsyllabic and word boundary (e.g., **u̯odr̥* 'water,' **m̥ĝh₂* (PREF) 'greatly'; an *h* with a subscript number following is one of the 'laryngeal' consonants discussed below). Similarly the two glides, *y* and *w* (or *i̯* and *u̯*), were in complementary distribution with the high vowels *i* and *u*; syllabic *i* and *u* occurred between nonsyllabics or between a nonsyllabic and word boundary (e.g., **nizdos* 'nest,' **peri* 'around,' **h₂usōs* 'dawn,' **upo* 'under'), and nonsyllabic *i̯* and *u̯* occurred adjacent to a vowel (e.g., **i̯aĝ-* 'worship, sacrifice,' **h₂u̯eh₁-* 'blow,' **neu̯os* 'new'). The nasals, liquids, and glides are therefore usually grouped together in IE studies under the label 'resonants.'

The syllabic resonants usually did not survive as such into the attested daughter languages, but typically developed epenthetic vowels (as Lith. *vilkas* 'wolf' < **u̯l̥kʷos*) or, in the case of syllabic nasals in Indo-Iranian and Greek, lost their nasality (thus, Vedic Skt. *tatás* 'stretched' < **tn̥tos*, Gk. *aga-*'greatly' < **m̥ĝh₂-*). But **r̥* survived intact into Indo–Iranian and prehistoric Greek (as evidenced by the metrical shape of certain words in the Homeric epics). The 'long' syllabic resonants are discussed later.

When the glides are the second element of diphthongs, notational practice fluctuates between writing them as syllabic or not (*ei/ei̯*, *au/au̯*, etc.); the notation *ei, au,* and so on is used here.

The single IE sibilant *s* was allophonically voiced to *z* before voiced stops, as in **nizdos* 'nest,' underlyingly **ni-sd-o-* '(where the bird) sits down' (with *-sd-* from the root **sed-* 'sit') > Russ. *gnezdo* (with later addition of *g-*), Eng. *nest*.

Laryngeals

Discovery We come now to the final set of consonants, dubbed 'laryngeals.' They were discovered by the young Ferdinand de Saussure, who in a brilliant monograph published when he was only 21 (Saussure, 1878) deduced their former existence from close analysis of morphophonological behavior of different classes of words. At the time, no IE language was known that actually preserved these sounds as consonants. Saussure theorized that there were two such sounds, which he termed 'sonant coefficients' (*coéfficients sonantiques*); his immediate followers, Hermann Möller (Møller) and Albert Cuny, expanded the number to three, which is now the standard accepted inventory. The term 'laryngeal' was not applied to them until 1911, by Möller, who borrowed it from Semitic linguistics.

It is usually averred that the laryngeal theory was not vindicated until 1927, over a decade after Saussure's death, when Jerzy Kuryłowicz discovered that the newly deciphered Hittite language contained a consonant (transliterated *ḫ*) appearing in many of the places for which Saussure had predicted a 'sonant coefficient.' Although this discovery was, of course, important (and dramatic) and provided us for the first time with consonantal reflexes of the laryngeals, in fact nearly all the advances in laryngeal theory both before and after Kurylowicz (1927) have flowed from material in Greek and Indo–Iranian, not Anatolian, and the theory had already assumed essentially its modern form by the 1910s (see especially Cuny, 1912). Even without Anatolian, in other words, the evidence for laryngeals in PIE is extremely strong.

That the laryngeals were consonants is certain (and was proved by Cuny), and that they were fricatives practically so. But precisely which fricatives is a matter of debate; for this reason, they are usually written algebraically as h_1, h_2, h_3, or with any of several alternate notations such as $ə_1$, $ə_2$, $ə_3$; H_1 H_2 H_3; and, in older literature, *E, A, O*. (According to a widely followed hypothesis, h_1 = [h] or [ʔ], h_2 = [ħ], and h_3 = [ʕ].) A capital *H* or, in older notation, schwa (ə) is used as a cover symbol for a laryngeal that cannot be identified more precisely, as in the root **bhuH-* 'be.' Although the usually accepted number of laryngeals is three, minority competing views have posited as few as one to as many as 15 or more.

Effects and Reflexes of Laryngeals The reconstruction of the laryngeals is supported by both direct and indirect evidence; here the latter is presented first. The indirect evidence consists in the effects the laryngeals had on neighboring sounds, particularly short vowels. A laryngeal following a short vowel disappeared while compensatorily lengthening the vowel: **dheh₁-*'place' > **dhē-* (as in Gk. *títhēmi* 'I place,' Eng. *deed*); **pih₂u̯on-* 'fat, fertile' > **pīu̯on-* (as in Vedic Skt. *pīvan-*). The second and third laryngeals

also had the property of 'coloring' an adjacent (short) *e* to *a* and *o*, respectively: ****h₂ent-*** 'front, forehead' > ****h₂ant-*** (> Hitt. *ḫant-*); ****steh₂-*** 'stand' > ****stah₂-*** > ****stā-*** (as in Lat. *stā-re* 'to stand'); ****h₃erbh-*** 'change status' > ****h₃orbh-*** (> Hitt. *ḫarp-* 'move from one (social) sphere to another,' Lat. *orbus* 'orphan'); ****ĝneh₃-*** 'know' > ****ĝnoh₃-*** > ****ĝnō-*** (as in Gk. *gignóskō* and Lat. (*g*)*nō-uī* 'I know'). As the last set of examples illustrates, coloring happened irrespective of whether the laryngeal preceded or followed the *e*. (An adjacent long *ē* apparently resisted coloring, a phenomenon known as Eichner's law, Eichner, 1973; examples include Hitt. *meḫur* 'time' < **mēh₂u̯r̥*, from the root **meh₂-* [> **mā-*] seen also in, e.g., Lat. *mā-ne* 'at an early time.')

The direct reflexes of the laryngeals are of two kinds, consonantal and vocalic. Only the Anatolian languages preserve uncontroversial consonantal reflexes, as in Hitt. *ḫant-* and *ḫarp-*; corresponding to the former, note also Cuneiform Luvian *ḫant-* and Lycian *xñt-*. In these two examples, a laryngeal is preserved prevocalically; but postvocalic laryngeals were often preserved as well, as in Hitt. *paḫš-* 'protect' < **peh₂s-*(cf. Lat. *pās-tor* 'shepherd') and Lyc. first-person singular PRET *a-xã* 'I did' < **-h₂om*. This, together with some other evidence especially from Indo–Iranian, shows that, whereas coloring had already happened within PIE, loss and compensatory lengthening either partially or completely postdated the breakup of the protolanguage.

In the non-Anatolian languages, the only sure direct reflexes of the laryngeals are vocalic. Between nonsyllabic sounds, the laryngeals became 'vocalized,' meaning either they had syllabic allophones like the resonants or developed prop vowels. (The latter scenario means that the vocalic reflexes are technically not direct reflexes of the laryngeals but only of the prop vowels.) The vocalized laryngeals are preserved in most branches, usually as short vowels, typically *a* (as in PIE ***ph₂ter-**> Lat. *pater*, Old Ir. *athir*, Arm. *hayr*, Eng. *father*), but also *i* (Skt. *pitár-*) and, in the case of Greek, a unique and extremely valuable 'triple reflex': *e* from vocalized ***h₁** (e.g., *thetós* '(having been) placed' < ***dʰh₁tos**), *a* from ***h₂** (e.g., *patér-* < ***ph₂ter-**), and *o* from ***h₃** (e.g., *dotós* 'given' < ***dh₃tos**). Whereas most languages that have vocalic reflexes of vocalized laryngeals have them only between consonants, the laryngeals were vocalized also word-initially before vowels in Greek, Armenian, and the fragmentarily attested Phrygian (e.g., ***h₂nēr*** 'man' > Gk. *anḗr*, Arm. *ayr* (earlier ***anir**), Phryg. *anar*; ***h₁regʷo-*** 'darkness' > Gk. *Érebos* 'Underworld'). Again, only Greek has a triple reflex here; Armenian and Phrygian have only *a-* and do not consistently show word-initial reflexes at all. In the other (non-Anatolian) branches, only indirect evidence of such laryngeals is found, especially the lengthening of preceding vowels in compounds (e.g., Skt. *sūnára-* 'having good men' < ***h₁su-h₂ner-o-**); otherwise, they disappeared without a trace.

Claims have been made that laryngeals sometimes 'hardened' into stops, typically velars, as in the Italic feminine agent–noun suffix *-trīc-* (< PIE ***-trih₂-**) and in the Armenian word for 'fish,' *jowkn* (perhaps < ***ĝhdhuH-**). These outcomes are controversial and only sporadically attested.

Laryngeals have also been used to explain the voiceless aspirated stops, mentioned previously. A second laryngeal frequently aspirated a following voiceless stop, as in Skt. *vétt**h**a* 'you (SING) know' < ***u̯oid-th₂e**, cf. Gk. (*w*)*oī**st**ha*.

Long Syllabic Resonants Older scholarship posited for PIE a set of long syllabic resonants, *m̥̄, n̥̄, r̥̄, l̥̄*. These are now understood to have been sequences of regular syllabic resonant plus laryngeal (cover symbol *R̥H*). Different outcomes are attested for different branches, including resonant plus long vowel (e.g., Lat. *strātus* 'spread out, strewn' < ***str̥h₃tos**), long vowel plus resonant (Skt. *pūrṇá-* 'full' < ***pl̥h₁no-**), vowel–resonant–vowel (Gk. *bálanos* 'acorn' < ***gʷl̥h₂-no-**), and long vowel (Skt. *yātar-* 'husband's brother's wife' < ***i̯n̥h₂ter-**). Again only Greek distinguishes reflexes of the different laryngeals in these sequences; thus, compare Lat. (*g*)*nātus* 'born' with Gk. *-gnētos* 'born' < ***ĝn̥h₁tos**, Lat. *strātus* with Gk. *strōtós* < ***str̥h₃tos**. In Baltic, the outcome was ultimately a vowel plus resonant with acute intonation (as in Lith. *pìlnas* 'full' < ***pl̥h₁no-**, where the grave mark represents acute intonation); a syllabic resonant that was not followed by a resonant resulted in circumflex intonation (as in Lith. *vìlkas* 'wolf' < ***u̯l̥kʷos**). Acute intonation in Baltic can therefore serve as confirmatory evidence for the prior existence of a laryngeal.

Vowels and Suprasegmentals

Vowels and Diphthongs

PIE possessed five short vowels, *i*, *e*, *a*, *o*, *u*, and the corresponding long vowels *ā*, *ē*, *ī*, *ō*, *ū*. The daughter languages typically preserve the high vowels *i* and *u* intact (e.g., ***tri-** 'three-' in Skt., Gk., Lat., and Gaulish *tri-*, ***upo** 'under, below' in Skt. *upá*, Gk. *hupó*, Lat. *s-ub*). The mid and low back vowels *o* and *a* merged in several European branches: to *a* in Germanic and Baltic (e.g., ***ok̑tō** 'eight' > Germ. *acht*, Lith. *aštuonì*) and to *o* in Slavic (Old Church Slavonic *osmĭ*, cf. ***nas-** 'nose' > OCS *nosĭ*). Indo–Iranian merged all three nonhigh vowels to a vowel transliterated

a (phonetically [ə] in Indic, [æ] in Iranian); analogously, the long nonhigh vowels merged to *ā*.

Combinations of nonhigh vowel plus high vowel formed the diphthongs *ei*, *ai*, *oi*, *eu*, *au*, *ou*, *ēi*, *āi*, *ōi*, *ēu*, *āu*, *ōu*. These are best preserved in Greek (e.g., Gk. *leípō* 'I leave' < **leik^w-*, *teúkhō* 'I build' < **dheugh-*, *poinḗ* 'payment, penalty' < **k^{w}oin-*, DAT SING (FEM) *-āi* < **-āi*); note also Skt. LOC SING (*u*-stem) *-āu* < **-ōu*, Old Latin *duenōi* 'for a good man' with DAT SING from **-ōi*.

The long vowels have been the subject of some controversy since the advent of laryngeal theory. As previously discussed, the laryngeals lengthened a preceding short vowel when they disappeared; this fact has caused a number of specialists to reinterpret many (or, in extreme cases, most or all) long vowels as originally sequences of short vowel plus laryngeal. Most researchers take a middle path, recognizing that some long vowels must have been primes (especially the *ē* and *ō* that root vowels could assume in the lengthened ablaut grades). There is dispute, however, concerning the reconstruction of specific lexemes.

With the high long vowels *ī* and *ū*, this issue is particularly troublesome because there are genuinely few examples in which a laryngeal is not implicated. Controversy thus surrounds the proper reconstruction of words such as **ĝhdhūs* 'fish' and **h$_3$bhrūs* 'eyebrow,' in which there are no independent morphological or comparative reasons for positing a laryngeal (aside from, e.g., the controversial velar in Armenian *jowkn* 'fish' mentioned previously).

Stress and Accent

The attested daughter branches show two accentual systems. In one, represented by Italic, Celtic, Armenian, and Albanian, the accent is stress-based and is either fixed (as in the unvarying word-final stress of Armenian) or varies in a predictable fashion (as in Latin, where antepenults are stressed unless the penult is heavy). The other system is characterized by a pitch-accent whose position is mobile, that is, generally not predictable on the basis of phonological criteria. This system is characteristic of Indic, Greek, and Balto–Slavic and was also true of pre-Germanic at least as late as the operation of Verner's law (discussed next). Either prehistoric or synchronic mobility of the accent is also recoverable for Anatolian, Iranian, and Tocharian. The nature of the Vedic Sanskrit pitch accent (low-rising on the accented syllable) is comparable with that of Ancient Greek, and it has been plausibly argued (although it is not assured) that Verner's law in Germanic, in which certain onsets of interior accented syllables were voiced, was the result of a reanalysis of the low pitch on these onsets as voicing (voiced consonants have lower pitch than voiceless ones). The combined evidence of this phonological characteristic of Vedic, Greek, and Germanic, together with the shared trait of having nominal and verbal paradigms in which the position of the main stress moved in lockstep with changes in ablaut (as Anatolian, Iranian, and Tocharian also point to), guarantee for PIE a mobile pitch-accent system as well.

Not all words in PIE had a lexical stress. A variety of unstressed words can be reconstructed (e.g., **k^{w}e* 'and,' **(e)me* 'me (ACC SING)') that most likely were clitics prosodically dependent on preceding stressed words. Comparative evidence suggests that certain forms of the copula (**h$_1$es-* 'be,' whence Lat. *est,* Eng. *is*) were clitics as well. From the accentual behavior of verbs in Vedic (where main-clause verbs are written without accent marks unless fronted to clause-initial position), Greek (where they are stressed in a similar fashion to chains of clitics), and Germanic (where certain verbs do not participate in alliteration in verse, unlike fully stressed words), it is commonly thought that verbs in PIE were unstressed or clitics. But with very few exceptions, verbs do not diachronically undergo phonological reduction as clitics do. It is likelier that verbs were fully stressed underlyingly (as they are in Vedic and elsewhere) but, for independent and quasiuniversal reasons having to do with information content, frequently were acoustically less prominent or destressed.

Phrasal Prosody

The prosodic organization of phrases in PIE was probably similar to that of modern languages. Clitics formed clitic groups with neighboring fully stressed words; they may have also grouped together into clitic chains near the beginnings of clauses, as in Anatolian, Indo–Iranian, and Greek. The specific rules that licensed cliticization and that governed the interaction of phonological phenomena (e.g., external sandhi and cliticization) with syntactic phenomena (e.g., movement) cannot yet be determined, but work on this topic in the daughter languages proceeds apace (e.g., Hale, 1990) and will no doubt yield insights into the prosodic organization and prosody–syntax interface of PIE itself (*see* **Proto-Indo–European Syntax**).

Phonological Rules

Internal Changes

Internal Sandhi Regressive voicing assimilation caused the devoicing of plain voiced stops before voiceless consonants (e.g., **h$_2$eĝ-to-* 'led, driven' > **h$_2$eḱ-to-*, **h$_1$ēd-si* 'you (SING) eat' > **h$_1$ēt-si*) and the voicing of voiceless stops and *s* before voiced

stops (e.g., *-pd- (a form of *ped- 'foot') < *-bd- in Younger Avestan *fra-bd-a-* 'front of the foot,' *ni-sd-o- > *ni-zd-o- 'nest').

In Indo–Iranian, by a process known as Bartholomae's law, a cluster consisting of a voiced aspirate followed by a voiceless stop underwent progressive, rather than regressive, voicing assimilation, and the aspiration was realized at the end of the cluster. Thus, Vedic Sanskrit *labh-tá- 'deceived' became *labh-dá- and finally *labdhá-*. A PIE date for this change has been alleged by several scholars, but the alleged traces of it outside Indo-Iranian are few and far between, and the matter is disputed.

Clusters consisting of two dentals developed an epenthetic sibilant between them. The full sequence *-tst-* is preserved in Anatolian (e.g., Hitt. *ezzazzi* (phonetically /etstsi/, from earlier */etsti/) '(s)he eats' < PIE *h_1ē**tsti** < *h_1ē**d-ti**-). In the other branches, the cluster underwent simplification, either by losing the sibilant (Ved. *átti* '(s)he eats') or the first dental (e.g., Avestan *vista-* 'known,' Gk. (*w*)*istós,* both < *u̯itsto-< *u̯id-to-), or by becoming *-ss-* (e.g., Lat. *pas-sus* 'suffered' < *pat-to-, Germ. *gewiss* 'certain' < *(-) u̯id-to-).

A labiovelar stop was delabialized next to *u*. The standard example is Gk. *boukólos* and Welsh *bugail* 'cow-herder' from *g^wou-kolos, where *-kolos is delabialized from *k^wolos (root *k^wel- 'to move about, cultivate, herd') after the *-u-* of *g^wou- 'cow.' Contrast this with Gk. *ai-pólos* 'goatherd,' with *p* the regular outcome of expected *k^w.

Internal Simplifications and Losses Geminates appear to have been avoided in PIE. A geminate *ss* was simplified to *s*, as in the second-person singular *$h_1$esi 'you are' < *$h_1$es-si, reflected in Ved. *ási*, Gk. *eĩ* (< *eï < *ehi < *esi). Geminate dentals arising from dental-plus-dental sequences were, as previously seen, broken up with an epenthetic sibilant.

Certain compounding and reduplication processes appear to have resulted in loss of laryngeals in the second compound member. The exact description of this change is as yet unclear, but examples include Gk. *neognós* 'newborn,' with *-gnos* from *-ĝnos rather than *-ĝn̥$h_1$os (root *ĝenh$_2$- 'beget') and, from the same root, Gk. *gígnomai* 'I am born' < *ĝi-ĝn-o- rather than *ĝi-ĝn̥h_1-o-. Laryngeals were probably subject to loss in other environments as well, although analogical change has often made the evidence difficult to work with.

It has been reasonably speculated that the prehistoric origin of the IE zero-grade (the form of a root when it drops its ablauting vowel, as in *sd- 'sit' in *ni-sd-o- 'nest') was the syncope of the ablauting vowel when not under the word-stress. However, because some stressed zero-grades are securely reconstructible (e.g., *h_2ŕ̥tḱos 'bear'), this must have happened well before the stage of PIE directly reachable by reconstruction.

Syllabification

Words were syllabified from right to left. The usual rules applied: Single consonants between vowels were syllabified as onsets, and word-internal consonant clusters were split between adjacent syllables. It is possible that *muta cum liquida* clusters (e.g., *tr, kl*) were syllabified as onsets, but the evidence from the daughter languages is contradictory. A sequence of two or more segments that had both syllabic/vocalized and nonsyllabic allophones (i.e., high vowels, resonants, or laryngeals) were syllabified from right to left as alternately syllabic and nonsyllabic. Thus, for example, *h_1n$h_3$mnbhi- 'with names' was syllabified *h̥$_1$.nh̥$_3$.mn̥.bhi- (> pre-Gk. *enomaphi, Gk. ultimately *onómasi* after subsequent changes).

But sometimes the expected output of these rules was undone by morphological analogy. For example, one of the present stems of the verbal root *i̯eug-, *i̯ug- 'yoke' was *i̯ung- rather than expected **iu̯n̥g-; the last form, if it ever existed, was replaced by a form that more closely resembled the root form *i̯ug-. In addition, there were dialectal differences: The feminine suffix *-ih̥$_2$ was syllabified as *-i̯h̥$_2$ (> *-i̯a) in Greek and Tocharian but as *-ih$_2$ (> *-ī) elsewhere. These may represent the generalization of different external sandhi variants.

The presence of a morphological boundary is also the likely reason why derivational morphemes such as the privative prefix *n̥- 'un-' remained syllabic even before vowels; instead of being realized as a nonsyllabic *n-*, it was rather realized as *n̥n-, with a nasal stop acting as a transition between the two syllabics. This is the source of the *-n-* in, for example, Skt. *anudrá-* and Gk. *ánudros* 'without water' from (morphological) *n̥-ud-ro-.

According to the principle known as Sievers's law, syllable weight affected the realization of clusters ending in glides: a cluster -Ci̯- or -Cu̯- was broken up to -Ci i̯- -Cu u̯- if the preceding syllable was heavy and if the glide began the last syllable of the word. Thus, Gothic *haírdeis* 'shepherd' comes from *herdijas, by Sievers's law from *herdjas (vs. *harjis* 'army' with no epenthesis, pre-Germanic *har-jas). An analogous epenthesis in word-initial clusters, called Lindeman's law, is treated in later discussion.

Phonotaxis

Consonant Clusters Word-initial consonant clusters were mostly subject to familiar constraints imposed by one or another version of the Sonority Sequencing Principle. In the main, consonants were sequenced in

order of increasing sonority, with most combinations of stops or *s* and resonants licensed. Certain ones are not found, perhaps accidentally, such as *g^whl-*. Sequences of resonant plus stop were common word-initially but, by the usual rules, did not form a tautosyllabic cluster (e.g., **m̥ĝh₂-* 'greatly'). Laryngeals were also common word-initially before resonants (or, much less commonly, stops), but it is not entirely clear how these were pronounced. As previously noted, in Greek, Armenian, and Phrygian, such laryngeals were vocalized; but in all the other branches they disappeared, suggesting that they could also be nonsyllabic. Probably the vocalized and nonvocalized pronunciations were sandhi variants depending on the final sound of the preceding word, with the vocalized variants generalized in some dialects.

Certain stop-plus-stop onsets were also allowed, in particular the so-called 'thorn clusters,' which (according to current understanding) consisted of a dental and a velar (in other, mostly earlier, views, one of the consonants was thought to be the fricative *θ* or *þ* (thorn)). These clusters have a rather bewildering variety of outcomes in the daughter languages: uniformly *kṣ* in Sanskrit, dental plus velar in Hittite and Tocharian, velar plus dental in Greek and Celtic, and single consonant elsewhere. Examples include **h₂r̥tk̑os* 'bear' (> Hitt. *ḫartaqqaš* (*-taqq-* phonetically /-tk-/), Skt. *ṛ́kṣaḥ*, Gk. *árktos*, Lat. *ursus*); **d^hĝ^{h}em-* 'earth' (> Hitt. ***takn-*** (phonetically /dgn-/); Cuneiform Luvian (*īn-*)***zagan*** 'in the earth' (phonetically /-tsk-/ or /-dzg-/), Melchert, 2003; Skt. ***kṣam-***; Toch. A ***tkam̨***; Gaulish ***xt****onio-* 'earthling, human' (phonetically /γd-/); Lat. ***humus*** 'ground'); and ******dhg^{wh}****(e)i-* 'waste away, perish' (> Skt. *ákṣita-* 'imperishable,' Gk. *áphthitos* 'imperishable,' Prakrit *jhīṇa-* 'wasted away'). Aside from thorn clusters, the only other word-initial stop-plus-stop cluster known for PIE is *pt-* (in derivatives of **pet-* 'fly').

There were also onset clusters consisting of three consonants. Almost all of these consisted of *s* plus stop plus resonant (e.g., **spreg-* 'scatter,' **splend-* 'glow'). The remaining triple clusters are scattered but typically have internal *-s-* or initial laryngeal (or both), as in the onomatopoetic root **pster-* 'sneeze,' in singular present optative stems such as **h₁si̯eh₁-* (root **h₁es-* 'be'), and in derived presents such as **h₁s-sk̑e-* (phonetically */h₁sk̑e-/) from the same root.

Co-occurrence Constraints within Roots Roots were of the general shape *CeC*, where *C* is a consonant. Certain classes of consonants could not co-occur within the same root: voiced (either plain or aspirated) and voiceless stops (type **bet-*, **bhet-*; with initial *s-*, however, it was allowed, type **steb-*, **stebh-*), voiced aspirates and voiceless stops (type **bhet-*; again, **stebh-* was allowed), and two plain voiced stops (type **bed-*). Exceptions, such as **ped-* 'foot,' are known but rare.

Under the glottalic theory, the last of these restrictions would in fact be a restriction against the co-occurrence of two glottalized stops in one root, a restriction known from a variety of language families having such consonants. As noted earlier, it is not impossible that an early stage of pre-PIE had glottalized consonants and that the co-occurrence constraints date to that time, but this is not provable.

External Sandhi

A few word-final sound changes are ascertainable for the protolanguage. Final clusters consisting of resonant plus *s* lost the *s* with concomitant lengthening of the preceding vowel (Szemerényi's law), as in NOM SING **ph₂tēr* 'father' < **ph₂ters*. Word-final combinations of *u̯* and a nasal behaved somewhat similarly, losing the glide with compensatory lengthening of the preceding vowel (Stang's law): ACCUS SING **g^woum* (**g^wou̯m*) 'cow' > **g^wōm* (> Ved. *gā́m*, Gk. (Doric) *bõn*), and likewise ACCUS SING **di̯eu̯m* 'sky, Sky-god' > **di̯ēm* (> Ved. *dyā́m*, Gk. *Zẽn* 'Zeus'). This latter change is interesting in its violation of the usual rules of syllabification, where we would expect ***g^wou̯m̥*, ***di̯eu̯m̥*, just like in ACCUS SING **podm̥* 'foot' (> Gk. *póda*).

Word-final *-n* was lost after *ō*: **k̑u̯ōn* 'dog' > ** k̑u̯ō* > Ved. *-śvā́*, OIr. *cú,* Lith. *šuõ*, Hitt. *kuwaš* (with later addition of the regular NOM SING suffix *-š*); the *n* has been restored in Gk. *kúōn*. Note also the various *n*-less Latin nominative singulars of the type *homō* (Old Latin stem *homon-*) 'man' and *legiō* (stem *legiōn-*) 'legion.' Contrast Gk. *humḗn* 'membrane' < **sumēn*, with retained *-n*.

Voicing contrasts were probably neutralized word-finally in PIE. Word-initial sandhi phenomena are barely known; one that deserves mention is Lindeman's law, whereby word-initial consonant clusters ending in a glide (as in **di̯ēus* 'sky,' **k̑u̯on-* 'dog') were broken up by an epenthetic vowel homorganic with the glide (> **di̯ēus*, **k̑uu̯on-*) when the syllable ending thepreceding word was heavy. Sometimes the disyllabic variant was generalized, as in Gk. *kúōn* 'dog.'

Our knowledge of PIE phonology is in some respects gratifyingly detailed, but in others still only partially developed. The ongoing refinement of our methods will surely continue to add to the complexity of the picture, answering some old questions while raising new ones.

Introduction

Methodological Preliminaries; Definition of Terms

Reconstructing the syntax of a proto-language presents the historical linguist with special challenges. Phonological and morphological systems involve the alteration and manipulation of discrete units (phonemes and morphemes, respectively) that combine to form other discrete units (words) that are, to a large extent, memorized and therefore transmitted whole from generation to generation. Information about the phonological and morphological rules is therefore transmitted along with them. But syntactic rules operate to combine words into larger units (phrases and sentences) that ordinarily are not memorized, but constantly generated on the fly through recombination.

It is by now a well-established fact, though one whose ramifications are not always fully or consistently appreciated, that the transmission of grammars

across generations is discontinuous. Learners do not have direct access to the grammars (linguistic knowledge-states) of other speakers, but only to their output (the primary linguistic data). Grammars are created afresh in each individual on the basis of the outputs to which the individual is exposed. Since there can be more than one possible algorithm for generating any given linguistic string, learners' grammars may turn out to be different from the grammars of those around them; any differences are due to reanalysis of the primary linguistic data and the deduction of a different rule or rules from the rules in the source grammar.

The distinction between underlying rules and outputs – deep structures and surface structures, simply put – is a critical consideration for determining what it means to 'reconstruct syntax.' Unfortunately, this distinction is often ignored, especially with respect to the issue around which arguably most work in Proto-Indo-European (PIE) syntax has centered since the Chomskyan revolution and the study of linguistic universals: basic word-order. This term can refer to several very different things, including the statistically most frequent surface word-order, pragmatically neutral surface word-order (which may or may not be statistically the most frequent), and the order of the elements of a clause in their base positions in deep structure (assuming that there is one such order for any given language). In many PIE syntactic studies, there has been a parallel lack of precision in the use of the term 'syntax' itself: for the generative linguist, the term applies properly to the underlying syntactic rules in the grammar that must be deduced from the behavior of surface structures; for many other researchers, however, the term applies to the surface structures themselves. In the strict sense of syntax as a system of rules that places phrasal and clausal constituents in specific structural positions, word order is not syntax, but a by-product of it.

Thus 'reconstruction of PIE syntax' should strictly refer to the reconstruction of the underlying syntactic rules of PIE. Such an enterprise, however, may seem to be an exercise in futility, since underlying syntactic rules are normally deduced from surface word-orders, yet practically no surface word-orders can be reconstructed for PIE and no native speakers of either PIE or its ancient daughters are left whose intuitions can be used to test theories against. As we will see in the following survey, however, the situation is not quite so dire.

The general inconsistencies of methodological approach noted above also play out in the syntactic study of the ancient daughter languages. Much more work needs to be done on establishing theoretically sophisticated analyses of the underlying syntactic rules of Greek, Latin, and their sisters before much progress can be made on figuring out what sorts of systems they could ultimately be reanalyses of. Linguistic reconstruction involves not only the reconstruction of proto-languages, but also the reconstruction of history, as it is part of the comparative linguist's task to account for the development of the daughter languages. (One must 'reconstruct forwards' as well as reconstructing backwards.) Unfortunately, our understanding of the mechanisms of syntactic change – what sorts of syntactic reanalyses are possible during grammar acquisition – is very much in its infancy, in spite of some progress in the last few decades. A proper theory of the development of the syntax of the Indo-European (IE) languages is therefore not yet attainable.

Our picture of the syntax of the oldest daughter languages in the family is incomplete not only by virtue of the absence of native speakers, but also by virtue of the nature of the texts that **are** preserved. Many ancient IE societies preserved only those texts having cultural significance, such as sacred texts, laws, myths, poetry, and the like. The language used in these genres often departs widely from ordinary speech. For some languages (even one as familiar as Latin) we are much better informed about high literary styles than we are about colloquial ones. Different styles and registers are characterized in part by different syntax, which means it is important to compare the syntax of sentences in identical genres across the family (e.g., Hittite and Latin legal language).

This correspondence of different syntax with different style or genre can be very useful. The Homeric epics evince both verb–object and object–verb word orders with great frequency. But in a semantically well-defined subset, word-orders are often found to be less varied; for example, proverbs and other traditional sayings in Homer are almost always object–verb. Proverbs and their syntactic properties in Homer can then be compared with proverbs in cognate traditions, and it turns out they share strikingly similar features in syntax and expression (Watkins, 1976). Since proverbs are traditional and can preserve archaic or otherwise exceptional constructions, they are especially useful data for syntactic reconstruction.

Care must be taken with respect to translation literature, which forms an important part of the corpus especially of Gothic (where a translation of the New Testament provides almost our entire extant corpus), Classical Armenian, and Old Church Slavonic. The translators of some of these texts stayed slavishly faithful to the word-order of the original, rendering their translations syntactically unidiomatic, in some cases apparently to the point of ungrammaticality.

The rapid development of syntactic theory over the past several decades, natural in a new field, has the disadvantage of rendering work that is beholden to a particular framework either quickly obsolete or controversial for other theory-internal reasons. In this article, we will therefore eschew adherence to a specific syntactic framework; specialists can easily translate the syntactic categories and positions referred to here into whatever schema best suits their purposes. Most of the illustrative examples below are drawn from Fortson (2004), Chapter 8.

History of the Field

Works on IE syntax in the 19th and first half of the 20th century often dealt with the use and behavior of morphological categories (nominal case, verbal mood, etc.), rather than with issues of word-order. The most famous exception is Wackernagel (1892), introducing the observation (now known as Wackernagel's law) that unstressed particles of various kinds usually appeared as the second element in their clause in the older IE languages (see Wackernagel's Law, below). Jacob Wackernagel and his contemporary Berthold Delbrück laid the foundations for historical PIE syntax with these and other studies.

Not much new work was undertaken in the intervening decades between their work and the Chomskyan revolution. In the 1960s and 1970s, researchers such as Winfred Lehmann and Paul Friedrich wrote several works on the clausal word-order of IE languages (including Lehmann, 1974 and Friedrich, 1975) – work that consisted in the main in statistical tallyings of the relative orders of different sentential constituents. These approaches have mostly been abandoned; see, for a well-known and important critique, Watkins (1976). Among the flaws in these studies was not recognizing that word-order is not equivalent to syntax, and that it is often the exceptional word-orders, especially those found in frozen phrases, rather than the word-orders that are commonest and generated by productive rules, that shed the most light on the syntactic history of a language. This important principle – reconstruct on the basis of exceptions – is of course also known from historical morphology.

Lehmann and Friedrich's works were influenced primarily by research into language universals, such as that of Joseph Greenberg. Simultaneously, some Indo-Europeanists were starting to incorporate Chomskyan generative syntactic models into their work. This has continued to the present day. Important works of this kind include those of Mark Hale on the syntax of clitics in Vedic Sanskrit (e.g., Hale, 1987) and Andrew Garrett on Anatolian clausal syntax (e.g., Garrett, 1990, 1992). A large number of articles on diachronic syntax within a generative framework have, however, been less than satisfying in that they present analyses that simply restate the data couched in theoretical terms (as, for example, a resetting of a parameter).

Critical for the advancement of the field are not simply good and sophisticated theoretical descriptions of synchronic facts, but diachronic explanations rooted in philologically ascertainable distributional patterns from surviving texts.

Phrasal Syntax of PIE

Noun Phrases

The daughter languages differ with respect to the relative order of adjectives (or dependent genitives) and head nouns within noun phrases. Typically adjectives precede their nouns in Hittite, Vedic, and Germanic, and follow them in Italic and Celtic; but within each of these languages there are exceptions that were sometimes lexically, at other times pragmatically, induced. In all these languages, however, and surely in PIE itself, adjectives agreed with their head nouns in gender, number, and case.

The ancient PIE languages allowed for the separation of nouns from their modifiers by one or more intervening elements, as in Cuneiform Luvian *alati awienta Wilušati* 'they came from steep Wilusa' Keilschrifttexte aus Boghazköy (KBo or KuB) 4.11:46); Greek *ándra moi énnepe Moũsa polútropon* 'tell me, Muse, of the resourceful man' (*Odyssey* 1.1), Latin *magnā cum laude* 'with great praise,' and Armenian *zyoys hatanem kenacʿ* 'I cut off *the hope of life*.'

Prepositional Phrases

In PIE, it is frequently averred that adpositions, adverbs, and preverbs were not separate categories. This is not likely to be true in any but the most superficial sense, given that these categories reflect rather different underlying syntactic behaviors. The statement is based in part on comparative evidence suggesting that preverbs had not yet univerbated with verbs, but were (partially? entirely?) free to occupy the same diversity of structural positions that is assumed for other adverbial elements. By the time of the oldest attested daughter languages, however, distinctions can be made between the behavior of these three types of words, at least in many cases (though not in all). Adpostions in Anatolian and Vedic are almost entirely postpositional (e.g., Hittite *šuḫḫi šēr* 'on the roof,' Vedic *jánāṁ ánu* 'among men'); the other languages either show a mix of pre- and postpositions (as in Avestan and Sabellic), or have almost entirely prepositions, sometimes with traces of postpositional use (e.g., Greek *toutṓn péri* 'about these things' and Latin *mēcum* 'with me'). Preverbs in Anatolian and

Indo-Iranian, and not infrequently in Homer, are still separate words: Old Hittite *š-aš šarā URU-ya pait* 'and he went up to the city' (KBo 22.2 rev. B 17' [Zalpa tale]; URU is a Sumerian word and, by convention, transliterated in capitals), Vedic *abhí yó mahinā́ dívaṃ Mitró babhū́va sapráthāḥ* 'Mitra the renowned who is superior to heaven by his greatness' (Rigveda 3.59.7), Greek *edētúos eks éron hénto* 'they put aside desire for food' (*Iliad* 1.469). (In classical philology, separation of preverb from verb is called tmesis, a misleading term since it is based on the point of view that the invariant univerbation of Classical Greek is the norm, whereas in fact separation of the two is historically original.)

By the time of the earliest attestation of the other languages, the preverbs had mostly become genuine prefixes, inseparable from their verb. However, in Celtic, Gothic, and residually in Archaic Latin, clitics could intervene between preverb and verb; e.g., Old Irish *atdom-indnastar* 'that **I** be brought' (Milan glosses 39[d]13), Gothic *frah ina ga-u-hva-sehvi* 'He asked him **if** he saw **anything**' (Mark 8:23). The 'separable prefixes' of German and Dutch may well be a direct continuation of the PIE situation, although this is not certain.

Syntactic analysis of these data must bear in mind that not all cases of separation of preverb from verb are structurally identical. The Avestan clause *apa vā yasāiti* 'or takes (it) away' (Yasna 11.5) begins with a preverb (*apa*) that is separated from its verb only because it must act as the host for the postpositive clitic conjunction vā 'or'. This is to be contrasted with e.g., *pairi uši vāraiia*ϑβəm 'cover (their) ears' (Yasht 1.27), where *pairi* 'around' has been fronted to clause-initial position for emphasis or contrast.

Syntax of the Clause

The Position of the Verb

It is usually claimed that PIE tensed clauses were verb-final. This claim rests on less secure comparative evidence than is usually admitted, however. Of the ancient IE languages, only Hittite is, under the most rigorous use of the term, strictly verb-final: in texts of all genres, the verb is always the last word in a clause except when it is fronted to clause-initial position for emphasis or contrast, or (very rarely) another constituent is right-extraposed to come after the verb. Latin is often described as a verb-final language, but a glance at any page of even ordinary Latin prose reveals a greater variety of possible positions for verbs (at least on the surface) than in Hittite, though verb-final clauses are considered normal. (One widely used Latin grammar puts it quite bluntly: "But the so-called normal arrangement is really rare" [Hale and Buck, 1903: 337].)

In many other styles there is considerably greater freedom. Again, to come to coherent grips with these data it is necessary to define what is meant by 'verb-final' – whether the term is supposed to refer to surface orders or underlying ones; and there is no one-to-one match between surface and underlying orders. A Latin clause like *eratque et bonus vir et innocens* 'and he was both a good and innocent man' (Cicero, *Brutus* 179) has the verb *erat* at the outset, but it may in fact be in clause-final position underlyingly if the complement *et bonus vir et innocens* has been heavy-NP-shifted rightward out of the verb phrase and the clitic conjunction-*que* has been moved by 'prosodic flip' or a similar process to the right of the left-most remaining constituent (the verb) in order to have a proper host to its left. Other analyses are possible as well, of course, which is why solving these issues has proved so vexing. It seems at any rate premature to make any claims concerning the word-order of clauses in PIE.

Like many of its descendants, both ancient and modern, PIE surely possessed nominal sentences, that is, those without an overt linking verb, of the type Old Persian *manā pitā Vištāspa* 'my father (is) Vištāspa' (DSf 12–13), Latin *tū coniūnx* 'you (are) his wife' (Vergil, *Aeneid* 4.113), Tocharian A *tsraṣiñ waste wrasaśśi* 'the strong (are) the protection of creatures' (Puṇyavantajātaka 2), and Russian *on russkij* 'he (is) Russian.'

The older IE languages are unanimous in their testimony that verbs agreed with their subjects in person and number. The most important exception is found in Anatolian, Old Avestan, and Greek, where neuter plural subjects take singular verbs, as in Hittite *apē-ya uddār* (neut. pl.) *QATAMMA lagāru* (sing.) 'let also those words fall over likewise' (KUB 2.3 iii 21–22; *QATAMMA* is Akkadian), Old Avestan yā (neut. pl.) *zī vāuuərəzōi* (sing.) 'the things which have been perpetrated' (Yasna 29.4), and Greek *hóssa te phúlla* (neut. pl.) *kaì ánthea* (neut. pl.) *gígnetai* (sing.) *hōrēi* 'as many as the leaves and the flowers that appear in their season' (*Iliad* 2.468). But this exception is only an apparent one from the PIE point of view: neuter plurals were originally collectives, and as such acted as singulars.

The possessive adjective **su̯o-* 'own' has syntactic peculiarities that may be mentioned at this juncture. While usually labeled a reflexive, **su̯o-* had broader usage than simply referring back to the subject of a sentence, as it could also be cross-indexed with newly introduced discourse material or to an older topic that has been just reintroduced. An example of the former from Sanskrit is Rigveda 8.2.7 *tráya índrasya*

sómāḥ sutā́saḥ santu devásya své kṣáye sutapā́vnaḥ 'Let the three somas be pressed for the god Indra in the soma-drinker's **own** house' (soma was the sacred intoxicating drink of ancient Hindu ritual). Here the possessive *své* refers not to the grammatical subject (*tráya . . . sómāḥ* 'the three somas') but rather to the soma-drinker (*sutapā́vnaḥ*). See recently Vine (1997) and references therein to earlier scholarship.

Movement Processes

The ancient IE daughters all have evidence for syntactic movement rules that shifted elements leftward to landing-sites at or near the front of a clause. Commonly seen, for example, is fronting of the verb to clause-initial position (topicalization) for emphasis or contrast: Hittite *ḫalziššai-wa-tta* DINGIR.MEŠ-*aš attaš* ^{D}*Kumarbiš* 'Kumarbi, the father of the gods, is calling you' (KUB 33.122 ii 11); Old Avestan *sraōtū sāsnā̊ fśəŋ́ḫiiō suiiē taštō* 'Let the bondsman (?), fashioned for benefit, hear the teachings' (Yasna 49.9); Armenian *erknēr erkin erknēr erkir* 'In labor was heaven, in labor was earth' (Movsēs Xorenacʿi 1.31). Existential verbs, verbs of speaking, and imperatives tend to be topicalized, as in Latin *est in cōnspectū Tenedos nōtissima fāmā īnsula* 'within sight there is a most famous island, Tenedos' (Vergil, *Aeneid* 2.21–22). Apparently topicalization of the verb happened frequently enough in some areas that its verb-initial word-order became reanalyzed as unmarked, as notably in Insular Celtic. But topicalization could cause any element to be fronted, e.g., from Hittite, *irma-šmaš-kan* dāḫḫun 'sickness I have taken away from you' (KBo 17.1 i 12'), *ammel-ma tarnumar ŪL pāi* 'but my release he won't give' (KBo 32.15 iii 16), *šarā-kan namma eḫu* 'come up again!' (KUB 33.84+ iv 11'). It is reasonable to suppose that topicalization was a syntactic process in PIE.

The cross-linguistically familiar process known as WH-movement (movement of an interrogative, or WH-word, towards the beginning of a clause or sentence) has also been posited for the proto-language on the basis of comparative evidence. Both topicalization and WH-movement were possible in the same clause, with the topicalized element (underlined in the following examples) preceding the WH-moved element (boldfaced), as in Hittite *ammuqq-a* ***kuit*** *ḫarkun* 'And also (that) **which** I had' (Apology of Hattusili III, iv 69) and Vedic Sanskrit *jātám* ***yád*** *enam apáso ádhārayan* '**when** the craftsmen held him, just born' (Rig Veda 3.2.7). Since, according to one commonly held analysis, WH-movement moves an element into the complementizer position and is responsible for the placement of subordinating conjunctions and relative pronouns as well as WH-words, topicalization around the complementizer slot produced word-orders not found in English. The details differ from language to language; in Latin, for example, all the words in a subordinate clause save one could appear before the subordinator. (It is still uncertain what the syntactic rules were that generated such word-orders.)

Wackernagel's Law

Jacob Wackernagel in 1892 published a lengthy study of clausal word-order in IE, in which he made the observation, now enshrined as a 'law' with his name, that unstressed clitic particles preferentially appeared second in their clause. Thus from, e.g., Sanskrit the unstressed object pronoun *tvā* 'thee' appears second in *ā́ tvā mántrāḥ kaviśastā vahantu* 'Let the spells recited by the poets lead you hither' (Rigveda 10.14.4), and in Greek the connective particle *dé* 'and, but' is second in the formulaic Epic line *ẽmos d' ērigéneia phánē rhododáktulos Ēṓs* 'but when early-born, rosy-fingered Dawn appeared' (*Iliad* 1.477 and passim). It has since been learned not only that the process is not limited to IE, but that within IE the term really covers at least three separate processes that all conspire to place different classes of left-leaning unstressed elements second within their clause most of the time (Hale, 1987).

Under this more modern account of Wackernagel's law, a distinction must be made between enclitics that have scope over a single word or constituent (word-level clitics), those that conjoin or disjoin sub-clausal constituents or whole clauses (sentence-connective clitics), and those that have scope over a whole clause or sentence (sentential clitics). Word-level clitics are often emphasizing particles, e.g., Hittite *-pat* (as in *nu-wa-za apun-**pat** eši* 'occupy **only** that (land)' [KUB 14.1 obv. 19]), or set the word to which they are attached in contrastive focus (e.g., Vedic *cid* in *pra-cyāváyanto ácyutā* ***cid*** 'the ones who move **even** unmovable things' [Rigveda 1.85.4]). Such particles obviously appear second in their clause only if the word they are attached to happens to come first in its clause. This is also true of sentence-connective clitics, typically words for 'and' and 'or' (e.g., *ca* 'and' in Vedic *ágna índraś* ***ca*** 'o Agni **and** Indra' [Rigveda 3.25.4], or *-ue* 'or' in Latin *silua alta Iouis lūcus**ue** Diānae* 'the high forest of Jupiter **or** the grove of Diana' [Vergil, *Aeneid* 3.681]; note that here the clitic has scope over a whole phrase and is attached to the first word within that phrase). The sentential clitics include various sentential adverbs, as well as the clitic personal pronouns. (IE languages typically distinguish between a set of fully stressed personal pronouns and a set of unstressed clitic forms.) Multiple sentential clitics can occur within a single clause,

forming chains, as famously in Hittite, e.g., *ḫaššuš-ma-wa-šši-za-kan*, where the four sentential clitics (added to *ḫaššuš-ma* 'but the king') are *-wa* (quotative particle), *-šši* (3rd sing. pronoun, dative), *-za* (reflexive particle), and *-kan* (modal particle). Here of course there is no question of strict 'second-position' placement, but note that the first particle in the chain is attached to the first available phonological host (the topicalized noun *ḫaššuš* 'king' plus the contrastive particle *-ma*).

Subordinate Clauses

Typical of IE relative constructions are the following, where the relative clause precedes the main clause and where the relative pronoun is picked up by an anaphoric pronoun in the main clause: (Sanskrit) ***yéna*** *imā́ víśvā cyávanā kr̥tā́ni* ... ***sá*** *janāsa índraḥ* (Rigveda 2.12.4) '(The one) **by whom** all these things have been made to shake ... **that**, people, (is) Indra'; (Greek) ***hós*** *ke theoīs epipeíthētai*, *mála t' ékluon* ***autoũ*** (*Iliad* 1.218), '**Whoever** obeys the gods, they listen **to him** as well'. Nominal antecedents often appear within the relative clause itself, agreeing in case with the relative (literal translations usually render such relatives as adjectives), as in Latin ***quem*** *agrum eōs uēndere herēdemque sequī licet*, ***is*** *ager uectīgal nei siet* (*Sententia Minuciorum,* CIL I^2 584.5) 'the field **which** (literally, which field) they are allowed to sell and pass to an heir, **that** field may not be taxable'.

As with subordinate clauses in general, the relative pronoun (or adjective or adverb) need not be the first word in the clause, but can be preceded by a topicalized element. In Hittite, definite relative clauses were obligatorily preceded by a member of the clause, while indefinite relative clauses began with the relative: thus *kuiš ḫaššuš āki* 'whichever king dies' is distinct from *ḫaššuš kuiš āki* 'the king who dies.' Second position of the relative became fixed in Insular Celtic, where the relative pronoun (fossilized as **yo*, uninflecting) appears either after the verb or between it and the preverb, e.g., Old Irish *ní latt aní ara-rethi* (Würzburg Glosses 6^b22) 'it is not yours that which you assail' (*ara-rethi* < **are-yo retesi*, where **are-* is the preverb). Gaulish, a Continental Celtic language, had the same uninflected relative, cliticized to the verb (e.g., *dugiionti-io* 'who serve', *toncsiíontío* 'who will swear (?)'), and in Baltic, the same relative stem (**i̯o-*) was affixed to adjectives to render them definite, e.g., *-ji* in Lithuanian (accus. sing.) *naũjąjį vařdą* 'the new name.' This reanalysis of the relative as a definiteness marker occurred also in Iranian; it is the source of the Modern Persian *ezāfe* construction, as for example in *ketāb-e naw* 'the new book', etymologically 'book which (is) new.' The antecedents are already in Old Persian, e.g., *karā hya manā* 'my army', literally 'army which (is) mine.' This example incidentally shows how the relative also came to be reanalyzed as a possessive marker (another function of the modern *ezāfe* construction), a reanalysis that has been recently mooted also for Carian (a fragmentary language of southwest Turkey and Egypt still imperfectly understood but recently recognized as Anatolian): *świnś upe arieś-χi ted* (M30) 'stele of Świn, father of Arie,' where *arieś-χi ted* literally means 'of Arie who (is) the father' (with -χi continuing the other PIE relative pronominal stem, **k^wi-*; see Hajnal in Crespo and García-Ramón, 1997).

The 'Phonology-Syntax Interface' of PIE

Abundant studies, especially from the 1980s on, have shown how syntactic structure and operations (movement in particular) can be reflected by the behavior of surface phonology. (For an overview see Inkelas and Zec, 1990.) Standard examples from English include lack of ability to cliticize *is* (i.e., contract it to 's) in structures of the type *I don't know who he is/*he's*, where the raising of the complement *who* out of the verb phrase blocks cliticization of the verb; its cliticization, though on the surface phonologically dependent on the preceding word, appears to require syntactically the presence of an *in-situ* complement.

Syntactic rules that have an effect on the phonological organization of sentences (i.e., on sentence prosody) are evidenced typically at the edges of prosodic domains. According to typical models, sounds are organized hierarchically into ever-larger groupings, or domains, starting with the mora or syllable, continuing through the word and clitic group, and ending with the clause or sentence (or utterance). Each such unit is the domain of a set of phonological rules. Since the edges of prosodic domains typically correlate with the edges of words, the behavior of cliticization and external sandhi phenomena have been especially extensively investigated for the clues they provide about the workings of underlying syntactic machinery.

As an example, in Greek, unaccented particles receive an accent if they occur before another such particle, as in the string *eí poú tís tina* 'if ever anyone (nom.) anyone (acc.)' (Thucydides 4.47), where the first three particles are normally unaccented when standing alone. However, in the phrase *doulíāi per en phrení* 'even in bondage in the mind' (Aeschylus, *Agamemnon* 1084), the unstressed enclitic particle *per* does not get accented in spite of occurring before the unaccented proclitic preposition *en*; the reason is that *per* and *en* do not belong to the same prosodic domain, but to different clitic groups, [*doulíāi per*]

and [*en phrení*]. *The accentuation rule therefore applies only to particles within the same clitic group*.

We are fortunate that Greek orthography provides us this piece of evidence of prosodic domain formation. The writing systems of the other ancient IE languages are of varying accuracy with regard to sandhi rules and similar phenomena. Sanskrit orthography is exceptional in recording numerous subphonemic details not normally represented in writing systems. The Hittites were quite meticulous in inserting spaces between words, but ran clitics together with their phonological hosts (or with other clitics in the frequent sentence-initial clitic chains) with no word breaks in between, indicating that these clitics united with their hosts as single phonological words. In Greek and Latin, it is often inscriptional remains that are the most valuable for extracting this kind of information, as standard orthography was heavily phonemic (especially in Latin) and suppressed the representation of most external sandhi phenomena. Thus a normatively spelled Latin sequence like *quod per* 'because through…' is sometimes spelled *quot per* on inscriptions, indicating word-final devoicing before an initial voiceless consonant.

Some authors modified existing orthographic systems in order to convey greater phonetic detail than was usual. In the Old High German writings of Notker Labeo, accents were placed on stressed words; definite articles were written without an accent before a non-branching noun phrase, but were written with an accent otherwise. This means that proclisis of the article was dependent on the syntactic 'heaviness' of the following noun phrase, a characteristic widely known for its numerous effects on other aspects of sentence construction as well, such as word-order.

Additional information can be gotten from metrics. Many of the classic texts in older IE languages are in poetry. Poetry is frequently mischaracterized as a repository of entirely artificial and unregulated grammatical excesses, but close study reveals that the syntax of poetic language is no less rule-governed than the syntax of prose. (One needs, to be sure, to differentiate between 'poetic grammar' and other grammars.) The Greek and Roman meters reveal numerous facts about prosodic domain-construction that are reflected in the allowable mapping of particular linguistic sequences onto metrical templates. For example, in several iambic and trochaic meters, a heavy syllable could be substituted for (resolved) by two light syllables, but only if the syllables belonged to the same word; the only allowable exception to this was if one of the light syllables was a clitic. Clearly a word-break between two fully stressed words was too great a prosodic boundary for the two short syllables to be comfortably equivalent to a single heavy syllable.

These are just some of the phonology–syntax effects that have been observed for the ancient IE languages, and it is reasonable to suppose that similar ones were characteristic of PIE itself. We have as yet little insight into the diachrony of prosodic systems, so it will be some time before we can confidently reconstruct any of these sorts of facts for the protolanguage. However, given that several clitics in the daughter languages are cognate and can be projected onto PIE (e.g., Sanscrit *ca*, Greek *te*, Latin *-que* 'and' from PIE $*k^we$), we know that PIE had clitics, which means it had clitic groups, and since the prosodic behavior of clitic groups does not vary widely or randomly among languages, it is reasonable to suppose that clitic groups in PIE were much the same as they are in languages of today. The same was surely true of other prosodic domains as well.

Protolanguage

D Bickerton, University of Hawaii, Manoa, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

It is essential to distinguish the term 'protolanguage' from the protolanguages reconstructed for the various language families of the world, e.g., Proto-Indo-European or Nostratic. These, if they existed, would be full-fledged human languages with a time depth of thousands (at most, a few tens of thousands) of years. Protolanguage is the hypothesized predecessor of all modern human languages, with a time depth measured in hundreds of thousands (perhaps millions) of years.

While the idea that language may have passed through more primitive stages has been around a long time, the first clear formulation of the protolanguage hypothesis appeared in Bickerton (1990). Several lines of argument supported the hypothesis. Language was unlikely to have emerged with all its modern complexity, so a more primitive antecedent was intrinsically plausible. Chomsky (1980) distinguished between the conceptual and the computational aspects of language (roughly, lexicon and syntax); evidence from early-stage pidgins (Bickerton, 1981) and early child language suggests that these two aspects are dissociable and that words (or manual signs) can be strung together without any syntactic structure. Early-stage pidgins in particular provide strong evidence, since these are spontaneously developed by adults with a fully developed language faculty but insufficient exposure to any potential common language for mastery of its syntax. The experience of speakers who have tried to acquire a first language after the critical period (such as Genie; see Curtiss, 1977) and who have consequently been unable to acquire full syntax suggests that protolanguage is more robust than modern human language, and might therefore be phylogenetically older. Finally, apes under instruction (Terrace *et al.*, 1979; Savage-Rumbaugh, 1986) have been able to acquire lexical items; however, without further explicit instruction (beyond passive exposure), they can also string such items together to form elementary, unstructured propositions.

What caused protolanguage to emerge? Early accounts focused on cooperative hunting or toolmaking, but since many animals hunt cooperatively and since toolmaking can be conducted or even taught (and indeed, among preliterate peoples, generally is) simply through observation and imitation, few researchers support such proposals nowadays (Gibson and Ingold, 1993; Hurford *et al.*, 1998). Currently, the favorite pressure is one that involves some form of social interaction, whether 'Machiavellian intelligence' (attempts to outwit and dominate other group members; see Humphrey, 1976), gossip as a substitute for grooming (Dunbar, 1996), or the development of a 'theory of mind' – the ability to realize that contents of another's mind need not be the same as one's own (Povinelli, 1996; Worden, 1998).

However, while many primates (certainly all the great apes, our nearest relatives) have an advanced social intelligence, employ Machiavellian strategies, and possess at least the rudiments of a theory of mind, no other species has even the most rudimentary language. This makes a strong biological argument against any 'social intelligence' approach, since a unique adaptation suggests an equally unique selective pressure. Since experiments with apes (Premack, 1976; Savage-Rumbaugh, 1986) have shown they can be trained to use languagelike systems, why did not 'social intelligence' pressures select for language in them, too?

An account based on foraging patterns (Bickerton, 2002) avoided these problems. The only other species with communication systems able to convey objective information are ants and bees. These, like humans (but unlike other apes), foraged under fusion-fission conditions (larger groups dividing into smaller units to cover areas large enough for group survival). Under such conditions, exchange of information becomes vital. Humans (but not apes, with smaller

Proto-Ugric

Definition

Proto-Uralic (or Proto-Finno-Ugric) is the protolanguage underlying the Uralic language family (also known as the Finno-Ugric language family). Since the genetic relationship between the Uralic languages is a fact established beyond doubt by the methods of comparative linguistics, Proto-Uralic may be understood as a fully developed and relatively homogeneous natural language, which was once spoken by an actual Proto-Uralic speech community in a limited geographical region, the Uralic homeland. Since, however, no written documentation is available for Proto-Uralic, and since even the earliest historically documented forms of the modern Uralic languages and branches (Hungarian, Permic, Finnic) date back less than 1000 years, the details of the Proto-Uralic lexical and grammatical structure remain hypothetical and can only be approached by the method of linguistic reconstruction. On the other hand, the Uralic comparative corpus is large enough to allow a fairly detailed picture to be created of Proto-Uralic. By applying the method of internal reconstruction to the Proto-Uralic reconstruction it is possible to reach even deeper time levels, which may be termed Pre-Proto-Uralic.

Mechanism of Breakup

The Uralic language family comprises nine relatively separate major branches, which are distributed in a wide trans-Eurasian belt from Scandinavia (Fennoscandia) and the Baltic region through European Russia to western and southern Siberia, as well as, historically, to northern Mongolia and the Baikal region. The documented branches are, from west to east: (1) Saamic (Saami), (2) Finnic (Baltic Finnic), (3) Mordvinic (Mordvin), (4) Cheremissic (Mari), (5) Permic, (6) Hungaric (Hungarian), (7) Mansic (Mansi), (8) Khantic (Khanty), and (9) Samoyedic. Although all these nine branches are unmistakably descendants of Proto-Uralic, the mechanism of the actual breakup of the Uralic protolanguage is open to two different interpretations, which differ in their definition of the relationships between the nine major branches.

In a linear model (comb model), all the major branches (or most of them) are understood as genetically equal, implying that Proto-Uralic was a relatively diffuse and widely dispersed entity from which the modern branches immediately derive. In a hierarchical model (family tree model), the Uralic branches are assumed to constitute a hierarchy of basically binary (in some cases ternary) relationships which, in the most commonly accepted interpretation, become increasingly deep towards the east, suggesting that Proto-Uralic had a compact core area in the east, from which it started its expansion in a westward-branching pattern.

Levels of Reconstruction

In the hierarchical (family tree) approach to the breakup of Proto-Uralic (which is here preferred, see Figure 1), it is normally postulated that the line of deepest genetic division within the Uralic family goes between Samoyedic (branch 1, in the east) and the rest of the family, also known as Finno-Ugric (branches 2 to 9, in the west). The Finno-Ugric branch, in turn, forms a hierarchically organized network of accumulative (sub)branches. Altogether, at least six genetically relevant levels of reconstruction can be distinguished, including the level of Proto-Uralic. A problem with the hierarchical model is that some of the deeper levels of reconstruction, notably the level of (actual) Proto-Finno-Ugric, turn out to be difficult to distinguish from Proto-Uralic itself, especially as far as phonological and morphological innovations are concerned. This is one of the reasons why the term 'Uralic' is often replaced by the more traditional term 'Finno-Ugric' (or 'Finno-Ugrian'). The hierarchical structure of the Uralic family is, however,

Figure 1 The levels of reconstruction in Uralic.

clearly visible in the lexical corpus, which allows a reasonably unambiguous division to be made between the two equal entities of Proto-Samoyedic and Proto-Finno-Ugric.

Principles of Reconstruction

Since Samoyedic and Finno-Ugric are, in the hierarchical approach, defined as the two main branches of the Uralic family, any feature that can be verified as Proto-Uralic has to be attested in both Samoyedic and Finno-Ugric. This circumstance has two consequences which have a potentially distorting effect on Proto-Uralic reconstructions. First, due to the greater internal diversification (and greater reconstructible depth) of the Finno-Ugric branch, the total Finno-Ugric comparative corpus is much larger than the available Samoyedic corpus. This means that, inevitably, many of the features reconstructible only for Proto-Finno-Ugric, but not attested in Samoyedic, may still derive from Proto-Uralic. Secondly, some of the features shared by Samoyedic with only the eastern branches of Finno-Ugric (especially Khantic, Mansic, and Hungaric, collectively termed Ugric) need not derive from Proto-Uralic, since they can also be due to shared post-Proto-Uralic areal innovations. In practice, however, the number of features shared only by Samoyedic and eastern Finno-Ugric seems to be relatively small, while the bulk of the currently known Proto-Uralic comparative corpus is based on material shared by Samoyedic and western Finno-Ugric (especially Finnic and Saamic). Although partly due to a bias in the research tradition, this situation also has a linguistic background, in that western Finno-Ugric and Samoyedic represent the two conservative margins of the Uralic area, while eastern Finno-Ugric (notably Ugric and Permic) represent the more innovative center of the language family. This is especially evident in details of syllable structure and segmental phonology, but also in morphology and lexicon.

Time Depth

The depth of Proto-Uralic can be roughly estimated on the basis of the size of the Uralic comparative corpus. Although Samoyedic and Finno-Ugric share a substantial amount of grammatical substance, the number of shared lexical elements that can be unambiguously reconstructed for Proto-Uralic is much smaller than the comparative corpus of most other major language families in Eurasia, including Indo-European. Importantly, the reconstructible Proto-Uralic lexicon does not contain words pertaining to agriculture or pastoralism, and the single item pointing to metal technology (**wäckä* 'metal, copper') seems to be a Eurasian *Wanderwort* that may have spread among the individual branches of Uralic in the post-Proto-Uralic period, or it may have primarily denoted native metal (copper or meteoritic iron) prior to the development of metalworking technology. By contrast, there are several Proto-Uralic words referring to a culture of hunters (**yïngsi* 'bow', **nyïxli* 'arrow') and gatherers (**pesä* 'nest', **muna* 'egg', **mura* 'berry'), who may also have known fishing (**kala* 'fish'). This would strongly suggest a Neolithic or Mesolithic cultural context. The absolute dating of Proto-Uralic depends, however, on how distant the speakers of Proto-Uralic were from the centers of post-Neolithic cultural innovation. Reasonable estimates would place Proto-Uralic at a depth of 5000 to 8000 years before the present.

Homeland

The method of linguistic paleontology suggests that Proto-Uralic was spoken in a boreal environment where several species of both European and Asian coniferous and deciduous trees grow together (**koxyi* 'birch', **jïxmi* 'bird cherry', **kaxsi* 'fir/spruce', **sïksi* '*Pinus cembra*'). The seasonal differences of the climate (**sungi* 'summer', **sada* 'rain', **lomi* 'snow') had given rise to technological adaptations (**suksi* 'ski', **suxi-* 'to row'). In conventional understanding, these criteria allow the Proto-Uralic homeland to be placed in the forest zone at the border between European Russia and Siberia, most probably in the southern Urals (hence also the name of the Uralic language family). This location also more or less corresponds to the linguistically postulated line of deepest genetic division, between Samoyedic and Finno-Ugric. However, the areal and demographic dominance of the European branches of Finno-Ugric has stimulated attempts to place the homeland further to the west, most commonly in the Middle Volga region, but even as far west as the Baltic region. Alternatively, a broad homeland, compatible with the linear model of internal taxonomy, has been proposed. Evidence for the various proposals has been sought from archaeological and, more recently, human genetic material, as well as from verified or alleged areal contacts with other language families, especially Indo-European. Even so, the basic arguments favoring a geographically compact and relatively eastern homeland have not been convincingly rejected.

Genetic Status

Proto-Uralic represents the ultimate node of genetic taxonomy that can be reached by the methods of

diachronic linguistics on the basis of the Uralic comparative corpus. Beyond Proto-Uralic, several higher-level relationships have been proposed with other language families and linguistic complexes, notably Indo-European, Altaic, and Paleo-Siberian. The external connection that has found most support among comparativists is the one linking Uralic with Yukaghir(ic), a Paleo-Siberian family in northeastern Siberia. The Uralo-Yukaghir hypothesis would fit well into the westward-branching pattern of the Uralic family, leaving Yukaghir(ic) as an additional easternmost (Para-Uralic) branch of the macrofamily. Unfortunately, the substantial evidence quoted in favor of this hypothesis, as well as of all other long-distance comparisons based on Uralic material, is insufficient to prove a genetic affinity. The only significant circumstance that links Uralic materially with other language families is the system of personal pronouns (1pl **m-*, 2pl **t-*), which is shared not only with Yukaghir(ic), but also with Indo-European, Turkic, Mongolic, Tungusic, and Kamchukotic (Chukchee-Kamchadal). This detail has never been satisfactorily explained, but it may have an areal and/or typological, rather than a genetic, background.

Areal Position

From the areal point of view, the Uralic language family is best characterized as a member of the trans-Eurasian Ural-Altaic belt, which also comprises the so-called Altaic complex in central and northeastern Asia, viz., Turkic, Mongolic, and Tungusic, as well as, more loosely, Korean(ic) and Japonic (Japanese-Ryukyu). The common features of all these language families are manifested in their general properties at various levels of grammatical structure (phonology, phonotactics, morphology, morphosyntax, syntax, discourse), and they seem to have been present already in the corresponding protolanguages, including Proto-Uralic. By contrast, neither Indo-European nor any of the Paleo-Siberian entities, including Yukaghir(ic), can be said to represent the Ural-Altaic language type. This suggests that Proto-Uralic was areally connected (either directly or indirectly) with the ancestral forms of the languages of the Altaic complex, a conclusion that is best compatible with the assumption of an eastern homeland of Proto-Uralic. Within Uralic, also, the strength of the Ural-Altaic features diminishes toward the west and north, suggesting the structural influence of other typologies.

External Contacts

The Ural-Altaic typology of Proto-Uralic suggests the presence of a prehistoric contact network, which extended from Uralic towards the area of the Altaic complex in the east. Depending on where exactly Proto-Uralic was spoken, this contact network may also have included other language families. Unfortunately, apart from the typological indicators, there are no uncontroversial traces, such as loanwords, of any protolanguage-level contacts between Uralic and other language families, including those of the Altaic complex. Contacts with Indo-European in the south and west, as reflected in the cultural vocabulary of all Uralic languages, seem to have begun only in the post-Proto-Uralic period separately for Samoyedic and the individual branches of Finno-Ugric. It is, however, likely that the Uralic family, during the post-Proto-Uralic period of expansion, has covered an unknown number of non-Uralic (subsequently extinct) languages and language families, which must have left traces in the structure and substance of the modern Uralic languages, especially in the west (the Baltic region) and north (the Arctic belt).

Syllable Structure

The two basic syllable types that can be reconstructed for Proto-Uralic are the open syllable (C)V and the closed syllable (C)VC. Syllables with an initial vowel (zero consonant) were permitted only in word-initial position. Pronominal roots and a few auxiliaries (such as the copula and the negative verb) were of the simple monosyllabic structure (C)V, while all significant word stems seem to have been of the disyllabic structure (C)V(C)CV, to which suffixal elements of the types -C and -(C)CV(-) could be added. As a result, consonant clusters were possible only at syllable boundaries, while both word initially and word finally only single consonants were permitted. No phonologically distinctive suprasegmental features can be reconstructed for Proto-Uralic, but there are indications that the disyllabic structure (C)V(C)CV functioned as the basic rhythmic unit, characterized by nondistinctive initial stress. The most common suprasegmental feature in the modern Uralic languages is the quantitative correlation of vowels, but in the light of the comparative evidence it is invariably of a secondary origin.

Segmental Phonology

The Proto-Uralic system of segmental phonemes is generally assumed to have had 10 distinctive vowels (Table 1) and around 17 consonants (Table 2). The vowels were organized into palatal-velar pairs, comprising two low vowels (**a*, **ä*), two mid-high vowels (**o*, **e*), two high rounded vowels (**u*, **ü*), and two high unrounded vowels (**ï*, **i*). In the consonant

	*r		
	*l		
*w		*y	

system, the stops and the nasals were divided into labials (*p, *m), dentals (*t, *n), palatals (*c, *ny), and velars (*k, *ng). The palatal stop has mainly continuant reflexes in the modern languages and may already in Proto-Uralic have been pronounced as a palatal continuant. There were also two liquids (*r, *l), two glides (*w, *y), and a dental continuant obstruent (*s). In addition, there was an affricate (*ts), which has mainly retroflex reflexes in the modern languages and is often reconstructed as a retroflex affricate or stop.

Finally, there were three consonants which are perhaps best classified as spirants (*d, *j, *x). The reconstruction of these segments is difficult due to the variety of their reflexes in the modern languages, with the important exception of one marginal branch (Saamic). Generally, the dental and palatal spirants (*d, *j) have merged with the systems of stops, liquids, and glides, while the velar glide (*x) has mostly no segmental trace at all. Not surprisingly, the velar (or postvelar or laryngeal) glide is the most controversial segment of the Proto-Uralic reconstruction. It is nevertheless a necessary tool for explaining certain phonotactic and prosodic phenomena in the modern languages, including the so-called primary vowel length in the Finno-Ugric branch, which seems to reflect the presence of an original syllable-final velar spirant (*Vx/_CV).

Phonotactics

Due to the limited size of the Proto-Uralic corpus, it is not always possible to make a clear distinction between systematic phonotactic features and accidental gaps. Some phonotactic restrictions can, however, be reconstructed. Most importantly, there seem to have been only two distinctive vowels in noninitial syllables, a low (or full) vowel (*a) and a high (or reduced) vowel (*i). Systematic restrictions pertaining to consonants seem to have included the exclusion of the velar nasal (*ng) and one of the liquids (the vibrant *r) from the word-initial position. Several specific restrictions seem to have concerned the spirants. None of the spirants (*d, *j, *x) is attested as the second component of a cluster, and the dental and velar spirants (*d, *x) are not attested in word-initial position. In intervocalic position, the velar spirant (*x) can only be reconstructed before the high vowel (*i) in a structural type (*Vxi) which has yielded monosyllabic reflexes in almost all branches. Evidence of geminate consonants is available only for the labial stop (*pp).

Morphophonology

The low vowel of noninitial syllables (*a), but not necessarily the high vowel (*i, also written as *e), is conventionally assumed to have been governed by palatovelar vowel harmony, valid both for word stems and for suffixes. Vowel harmony is synchronically present in many, though not all, branches of Uralic, especially in the west (Finnic) and east (Samoyedic), but also in the center (Hungarian). However, vowel harmony seems to be a relatively unstable phenomenon, which has appeared and disappeared separately in several individual Uralic languages. Even if it may have represented an actual phonetic tendency in Proto-Uralic, it cannot be reconstructed as a phonemic phenomenon. The same is true of the so-called consonant gradation, involving the alternation of strong (long) and weak (short) varieties of medial consonants (especially stops) in three marginal branches of Uralic (Saamic, Finnic, and Samoyedic). Both vowel harmony and consonant gradation are probably best seen as convergent tendencies, which have received a phonemic status only separately in the languages and/or branches concerned. Both phenomena have apparently been triggered by the pattern of initial stress inherited from Proto-Uralic. A third feature conditioned by stress is the so-called consonant stem formation, which involves the loss of a stem-final second-syllable (unstressed) high (or reduced) vowel (*i) before suffixal syllables beginning with a single consonant (*VCi-CV → *VC-CV). Derivational relationships such as *pidi- 'to be long/high'/*pid-kä 'long/high' suggest that consonant stems may have had a phonemic status already in Proto-Uralic.

Morphological Typology

Proto-Uralic is traditionally reconstructed as an almost perfectly regular agglutinative language, in

which the principal method of morphological marking was suffixation, used both for inflexional and derivational purposes. The regularity of Proto-Uralic may, however, be partly due to the distorting effect of the comparative method, which does not allow irregularities and morphophonological alternations to be traced to the protolanguage. In the actual Proto-Uralic language, agglutination may therefore have been accompanied by true morphophonological alternations, including flective features later lost in the modern languages. A flective feature that has occasionally, though erroneously, been reconstructed for Proto-Uralic is vowel ablaut (a nontransparent system of paradigmatic vowel alternations), which is synchronically present in a single eastern branch of Uralic (Khantic). However, even if Proto-Uralic cannot be shown to have contained nonagglutinative features, such features are likely to have been present in Pre-Proto-Uralic, and traces of them can possibly still be detected by an analysis of the Proto-Uralic lexicon and grammar by the method of internal reconstruction.

Parts of Speech

Nouns and verbs were distinguished in Proto-Uralic by separate sets of morphological markers, corresponding to the systems of nominal declension and verbal conjugation. The morphological class of nouns included also pronouns, numerals, and spatials (spatial nouns, used also as postpositions). Nouns could be turned into verbs (denominal verbs) and vice versa (deverbal nouns) by using derivative suffixes. There are, however, indications that the distinction between nouns and verbs was less clear in Pre-Proto-Uralic. This is particularly evident from the fact that several subsets of suffixes (the number markers, the personal markers, many derivative suffixes, and even some case endings) seem to have occurred with both nominal and verbal stems. Also, Proto-Uralic had a considerable number of ambivalent (noun–verb) stems of the type **pala* 'bite'/**pala-* 'to bite'. In some cases, the verbal function of an ambivalent stem seems to have conveyed an adjectival meaning (static verb), as in **pilmi* 'darkness, shadow, cloud'/**pilmi-* 'to be dark'.

Number and Case

The Proto-Uralic nominal paradigm (Table 3) comprised three numbers and at least six cases. The full case paradigm, which can be reconstructed only for the singular, comprised three general grammatical cases: the unmarked nominative; the genitive in **-n* and the accusative in **-m*; and three local cases: the locative in **-na*, the ablative in **-ti*, and the dative in **-ng*. The genitive had a double role, in that it was used both adnominally in its genitival function (possessive attribute) and adverbially as an instrumental (modal adverb). Additionally, at least two other modal forms, the caritive in **-kta* and the translative in **-ksi*, functioning as cases in some modern languages, can be traced back to Proto-Uralic. For the plural, only the basic form in **-t* and one oblique form (connective) in **-y* can be reconstructed, while the dual in **-kV-* (possibly from the numeral **käktä* 'two') may have lacked marked case forms altogether. The dual is attested only on the western and eastern margins of the Uralic family (Saamic, Ugric, Samoyedic), and its reconstructive status remains somewhat controversial in the details.

Table 3 The Proto-Uralic nominal paradigm

Singular	nominative	**-Ø*	basic form
	genitive	**-n*	possessor / instrument
	accusative	**-m*	object
	locative	**-na*	location
	ablative	**-ti*	movement from
	dative	**-ng*	movement to
Plural	nominative	**-t*	plurality
	connective	**-y*	plural possessor / object
Dual	nominative	**-kV-*	duality

Personal Markers

The exact shapes of the Proto-Uralic personal pronouns are virtually impossible to reconstruct, though the singular 1st and 2nd person pronouns may have been **min* and **tin* respectively, while the 3rd person pronoun may have had the structure **sVn*. The corresponding plural and dual pronouns had the same initial consonants, but were modified by paradigmatic vowel alternations and/or suffixation. There are indications that the plural pronouns may have incorporated the regular nominal plural marker (**-t*), but the dual pronouns (if present in the protolanguage) may have had a suffix different from the regular dual marker. From the suffixal use of the pronouns, two sets of morphological personal markers had arisen already in Pre-Proto-Uralic (Table 4). The markers of the one set may be characterized as basically predicative (predicative personal endings), since they referred to the subject of a finite verb, while the markers of the other set may be called possessive (possessive suffixes), since they indicated the possessor of a noun. Evidence from the eastern branches of the Uralic family (Ugric, Samoyedic) suggests, however, that the predicative markers could also be attached to nouns to indicate the subject of a nominal

Table 4 The Proto-Uralic personal markers

		Predicative /subjective	*Possessive /objective*
Singular	1	**-m*	**-mi*
	2	**-t / *-n*	**-ti*
	3	**-Ø*	**-sa*
Dual	1	**-mV-*	**-mV-*
	2	**-tV-*	**-tV-*
	3	**-kV-*	**-sV-*
Plural	1	**-ma-t*	**-ma-t*
	2	**-ta-t*	**-ta-t*
	3	**-t*	**-sa-t*

predicate (nominal predicative conjugation), while the possessive markers could be attached to verbs to refer to the subject of a transitive verb with a 3rd person definite or specific object (the so-called objective conjugation of verbs). Formally, the two sets may have been distinct only in the singular 1st and 2nd persons, which show more basic suffix shapes in the predicative set, and in the 3rd person forms, which in the predicative set take the number markers of the nominal declension instead of actual pronominal markers. A reconstructional problem is posed by the 2nd person singular marker, which in Samoyedic and one of the Finno-Ugric branches (Permic) seems to be based on an aberrant shape of the personal pronoun (**n-*). The 2nd person pronoun in these branches is of the regular type (**t-*), on which the dual and plural personal endings are also based. Corresponding aberrant pronouns of the 2nd person (**n-*) are actually attested in two Siberian branches of the family (Mansic and Khantic, areally united under the label Ob-Ugric), but their diachronic status is unclear.

Tense and Aspect

The plain stem of the verb, conjugated in persons, formed in Proto-Uralic a basic paradigm of predicative forms, which may have functioned either as a general present-future tense (as in Saamic and Finnic) or as an aspectually dependent temporally ambiguous unmarked aorist (as in Samoyedic), which would have referred to either a present tense (for imperfective verbs) or an immediate past tense (for perfective verbs). Other aspectual contents in Proto-Uralic seem to have been expressed by derivative suffixes (deverbal verbs), while other temporal forms were based on the predicative use of the nominal forms of the verb. Detailed reconstruction of the temporal-aspectual system of the protolanguage is impossible due to the functional variety of the reflexes of the individual markers in the modern languages. This may suggest that the system was not stabilized in Proto-Uralic.

Nominalization of the Verb

In spite of the presence of ambivalent stems functioning as both nouns and verbs, the dominant method of nominalizing verbs in Proto-Uralic was by suffixation. The nominal forms of the verb were morphologically nouns (with the forms of the nominal declension), but syntactically verbs (with the complements of the verb). Functionally, they may be characterized as both participles (actor forms) and infinitives (action forms), with no reconstructible distinction. The nominalizing suffixes, of which a large variety can be reconstructed, appear to have formed sets in which a single suffixal consonant (most typically **p*, **t*, **c*, **k*, **m*, **y*) could occur with three different vocalic structures: with a low vowel (**-Ca*), with a high vowel (**-Ci*), or with no vowel at all (**-C*). For most of these suffixes, only a very general nominalizing role can be reconstructed, but in the individual Uralic languages they typically appear with clear-cut functional distinctions. When used predicatively and conjugated in persons, they have also served as the basic source of finite temporal-aspectual and modal markers in all Uralic languages. One of the most obvious examples of this is the imperative paradigm, which seems to have been grammaticalized already in Proto-Uralic on the basis of one of the nominalizing consonants with two different vocalic structures (**-k/*-ka-*). In the imperative paradigm, the (inherently unmarked) 2nd person singular reference (**-k*) was exceptionally formed without an actual personal marker. Otherwise, nominalizing suffixes without a personal marker (but with number markers) are widely attested in the function of 3rd person forms of various finite subparadigms in the modern Uralic languages.

Adverbialization of the Verb

Adverbial case forms of the nominal forms of the verb probably occurred already in Proto-Uralic in converbial (gerundial) functions, indicating various types of subordinated predication. Only one such structure, the verbal caritive in **-mV-kta* 'without doing' and the corresponding nominal derivative (negative participle) in **-mV-kta-ma*, can be concretely reconstructed for Proto-Uralic. In addition, there is evidence that the plain verbal stem (without a nominalizer) could also take case endings, notably the instrumentally used genitive ending (**-n*), to mark a subordinated predicate (modal converb).

Negation

An important typological feature of Proto-Uralic (shared in the Ural-Altaic context with Tungusic) was the presence of the negative verb **e-*, which functioned as the syntactic main verb in all negative constructions. The negative verb took the regular verbal markers of predication and nominalization, while the semantic main verb to be negated stood in an invariant nominalized form termed the connegative (formally identical with the 2nd person singular imperative in **-k*), e.g. **kanta-m* 'I carry' : **e-m kanta-k* 'I do not carry'. The connegative is synchronically a feature of the marginal branches of the family (Saamic, Finnic, Samoyedic), but the verbality of negation is generally well preserved also in the other branches (with the exception of Hungarian).

Sentence Structure

The Proto-Uralic word order may with little ambiguity be reconstructed as having been of the Ural-Altaic head-final type, with the arguments preceding the verb (SOV) and with all attributes preceding the head noun (GAN). Embedded structures (relativization) and subordinate clauses were expressed with the help of nominalized verbal forms, with case endings functioning as the principal linkers between the components of the complex sentence. The agent–patient relation was indicated by the nominative–accusative strategy (with an unmarked nominative and marked accusative), but the presence of an apparent suffixal element in what would seem to have been the basic forms of certain personal pronouns (the singular pronouns **mi-n*, **ti-n*, **sV-n*, and the interrogative pronoun **ke-n* 'who') might point to a system of agent marking (possibly ergative) in an earlier stage of Pre-Proto-Uralic. An idiosyncratic syntactic feature that can be reconstructed for Proto-Uralic is the lack of accusative marking in the object of a 2nd person singular imperative predicate. In such sentences, the unmarked object could also be analyzed as the subject of a nominalized verbal predicate (formally unmarked for person).

Lexicon

In addition to a considerable paradigm of relatively unambiguous morphological and derivative markers as well as a smaller number of phonologically unstable pronominal roots and auxiliaries, the currently known Proto-Uralic lexicon comprises fewer than 200 fully satisfactory etymologies. Apart from the items of basic (apparently Neolithic) cultural vocabulary and some geographically diagnostic (boreal) botanical and climatic terms, the common lexicon comprises words pertaining to the natural elements (**weti* 'water'), topography (**toxi* 'lake'), astronomy (**kïxi* 'moon'), anatomy (**cilmä* 'eye'), physiology (**elä-* 'to live'), sensations (**päywä* 'warmth'), emotions (**peli-* 'to fear'), kinship (**ïppi* 'father-in-law'), and social interaction (**mexi-* 'to give'). The small number of Proto-Uralic etymologies diminishes considerably the prospects of distant comparisons with other language families, including Yukaghir(ic), Indo-European, and the Altaic complex. Few Proto-Uralic items have credible look-alikes in other language families, allowing them to be regarded as possible Eurasian *Wanderwörter* (an example is **nimi* 'name'). Importantly, although the Finno-Ugric languages share basic numerals up to six, only two numeral stems (**käktä* 'two', **witi* 'five/ten') are shared with Samoyedic and can be reconstructed for Proto-Uralic. All higher numerals (including seven) in the modern Uralic languages are either borrowings (mainly from Indo-European) or internal innovations (often etymologically transparent). The scarcity of the native numeral stock is another important argument in favor of an early dating for Proto-Uralic.

History of Research

Although the genetic unity of the Finno-Ugric languages was established already in the late 18th century, the connection between Finno-Ugric and Samoyedic was first seriously postulated by the Finnish ethnolinguist M. A. Castrén in 1845, and definitively demonstrated only by Heikki Paasonen in 1912–1917. Relevant questions pertaining to the emergence of the Uralic concept and the early development of Uralic comparative studies were discussed by G. J. Stipa (1990). The traditional Proto-Uralic lexical corpus was summarized in the etymological dictionary published under the editorship of Károly Rédei (1986–1988). A more advanced reconstruction of Proto-Uralic became possible only after further progress had been made in the internal diachronic analysis of the Samoyedic branch. The current principles of Uralic language comparison and Proto-Uralic reconstruction were discussed by Daniel Abondolo (1998). A critically evaluated and up-to-date database of Uralic diachronic phonology and lexicology was presented by Pekka Sammallahti (1988), whose corpus has most recently been complemented by corrections and fresh etymologies by Ante Aikio (2002). In spite of the obvious solidity of the Uralic language family, the prehistorical validity of Proto-Uralic was questioned by Angela Marcantonio (2002), who argued that the small size of the Proto-Uralic corpus allows an excessive margin of statistical

error. The conceptual mistakes inherent in this and other 'revolutionary' approaches to Uralic studies were discussed by Juha Janhunen (2001).

Proto-Indo–European Morphology

J H Jasanoff, Harvard University, Cambridge MA, USA

© 2006 Elsevier Ltd. All rights reserved.

General

Proto-Indo–European (PIE), like its earliest daughters (Hittite, Vedic Sanskrit, Avestan, Greek, Latin, etc.) was a highly inflected language. It is important to emphasize this fact in view of the many ways in which our view of PIE morphology has changed since the 1960s. For much of the 20th century, the burning questions in IE linguistics lay in the area of phonology, as scholars struggled to determine the number and character of the laryngeal consonants assignable to the protolanguage. It was only later, with the emergence of a consensus on laryngeals and the development of new methods of linguistic and philological analysis, that the 20th-century revolution in IE phonology began to spill over into morphology. Here the result was an even more radical rethinking of the traditional picture. The 'new look' of PIE morphology differs profoundly from the classical account by Brugmann (b. 1849) and newer works in the Brugmannian tradition. But attempts to portray PIE as a 'simpler' (i.e., less morphophonemically complex) language than its daughters have proved misguided.

The basic architecture of PIE was like that of any early IE language. The subject of a sentence stood in the nominative case and agreed with its verb in person and number; the verb was also marked for diathesis or 'voice' and for a variety of tense-aspect and modal categories. Nominal (i.e., substantival and adjectival) stems distinguished gender as well as case. An assortment of derivational processes allowed the formation of nominal and verbal stems from roots or simpler derived stems. Suffixation and ablaut, typically accompanied by movement of the accent, were the commonest devices for marking inflection and derivation. Prefixation as such was virtually unknown, but nouns and verbs combined freely with local particles (preverbs) in ways that tended to lead to the emergence of true prefixes in the daughter languages.

Although PIE distinguished sharply between nominal and verbal stems, a few generalizations can be stated for both. At the heart of every PIE noun or verb (pronouns are discussed separately) was a root. PIE roots were characteristically monosyllabic complexes of the form $*(s)C_1(C_2)EC_3(C_4)$-, where the symbols C_1, C_2, etc., stand for consonants and E stands for a variable vowel. All roots ended in a consonant; traditionally reconstructed preforms such as **dhē-* 'put' and **stā-* 'stand' are now known to have ended in a laryngeal (**dheh$_1$-*, **steh$_2$-*). Whether all roots also began with a consonant is less clear but often assumed. Certain consonant combinations (e.g., plain voiced stop + plain voiced stop; voiceless stop + voiced aspirate, in either order) were disallowed within a single root, a fact that may shed light on the prehistory of the PIE stop system. Some roots, such as **trem-* and **tres-*, both meaning 'tremble,' and **dreh$_2$-* or **drem-*, both meaning 'sleep,' seem originally to have contained an internal morpheme boundary. A boundary is obvious in cases such as **h$_2$u̯eks-* and **h$_2$eu̯g-* 'increase, grow,' where the final **-s-* is known to be an obsolete stem-formative.

Roots combined with one or more optional suffixes to form stems. PIE suffixes were of two canonical types, thematic and athematic. Thematic suffixes were of the form $*\text{-}(C_1)(C_2)(C_3)e/o$-, where the final element, called the thematic vowel, was realized as

Protolanguage

D Bickerton, University of Hawaii, Manoa, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

It is essential to distinguish the term 'protolanguage' from the protolanguages reconstructed for the various language families of the world, e.g., Proto-Indo-European or Nostratic. These, if they existed, would be full-fledged human languages with a time depth of thousands (at most, a few tens of thousands) of years. Protolanguage is the hypothesized predecessor of all modern human languages, with a time depth measured in hundreds of thousands (perhaps millions) of years.

While the idea that language may have passed through more primitive stages has been around a long time, the first clear formulation of the protolanguage hypothesis appeared in Bickerton (1990). Several lines of argument supported the hypothesis. Language was unlikely to have emerged with all its modern complexity, so a more primitive antecedent was intrinsically plausible. Chomsky (1980) distinguished between the conceptual and the computational aspects of language (roughly, lexicon and syntax); evidence from early-stage pidgins (Bickerton, 1981) and early child language suggests that these two aspects are dissociable and that words (or manual signs) can be strung together without any syntactic structure. Early-stage pidgins in particular provide strong evidence, since these are spontaneously developed by adults with a fully developed language faculty but insufficient exposure to any potential common language for mastery of its syntax. The experience of speakers who have tried to acquire a first language after the critical period (such as Genie; see Curtiss, 1977) and who have consequently been unable to acquire full syntax suggests that protolanguage is more robust than modern human language, and might therefore be phylogenetically older. Finally, apes under instruction (Terrace *et al.*, 1979; Savage-Rumbaugh, 1986) have been able to acquire lexical items; however, without further explicit instruction (beyond passive exposure), they can also string such items together to form elementary, unstructured propositions.

What caused protolanguage to emerge? Early accounts focused on cooperative hunting or toolmaking, but since many animals hunt cooperatively and since toolmaking can be conducted or even taught (and indeed, among preliterate peoples, generally is) simply through observation and imitation, few researchers support such proposals nowadays (Gibson and Ingold, 1993; Hurford *et al.*, 1998). Currently, the favorite pressure is one that involves some form of social interaction, whether 'Machiavellian intelligence' (attempts to outwit and dominate other group members; see Humphrey, 1976), gossip as a substitute for grooming (Dunbar, 1996), or the development of a 'theory of mind' – the ability to realize that contents of another's mind need not be the same as one's own (Povinelli, 1996; Worden, 1998).

However, while many primates (certainly all the great apes, our nearest relatives) have an advanced social intelligence, employ Machiavellian strategies, and possess at least the rudiments of a theory of mind, no other species has even the most rudimentary language. This makes a strong biological argument against any 'social intelligence' approach, since a unique adaptation suggests an equally unique selective pressure. Since experiments with apes (Premack, 1976; Savage-Rumbaugh, 1986) have shown they can be trained to use languagelike systems, why did not 'social intelligence' pressures select for language in them, too?

An account based on foraging patterns (Bickerton, 2002) avoided these problems. The only other species with communication systems able to convey objective information are ants and bees. These, like humans (but unlike other apes), foraged under fusion-fission conditions (larger groups dividing into smaller units to cover areas large enough for group survival). Under such conditions, exchange of information becomes vital. Humans (but not apes, with smaller

ranges, more abundant food supplies, and group-foraging patterns) would thus have been driven to exploit a substrate common to many relatively large-brained species, a rich conceptual structure whose units could be symbolized by sounds or manual gestures or both. With such a substrate in place, few if any neurological adaptations were needed for protolanguage to launch. The well-known fact that all languages can add freely to their vocabulary would then derive from properties of this conceptual-structure substrate, which is unbounded; moreover, this would have applied from the earliest stages of protolanguage, clearly distinguishing the latter from the closed-set, genetically based communicative systems used by all other animals.

Was protolanguage signed or spoken? Since Hewes (1973), numerous writers (e.g., Armstrong *et al.*, 1995; Corballis, 2002) have proposed an initial signed language. Two things can be said about this: first, there is no compelling evidence either way, and second, it is unclear whether the question has any importance. Most serious evolutionary issues, such as what caused protolanguage to emerge in just one species or what structural features distinguished it from modern human language, remain unanswered however this particular debate is decided. It is possible, indeed likely, that the earliest protolanguage mixed manual signs with vocal utterances – whatever worked communicatively would have been good enough.

The notion that some form of protolanguage preceded full human language is widely accepted. However, its precise nature remains controversial. For many writers, it was merely the first in a series of stages leading to full language (Pinker, 1994; Jackendoff, 2002); for others, no stage intervened between protolanguage and the earliest fully syntactical language, though grammatical morphology might not have developed immediately. Moreover, there has been considerable disagreement about the content and composition of protolanguage.

Slobin (2002) disputed evidence for protolanguage's lack of structure drawn from early child language on the grounds that children learning inflected languages (Turkish or Inuktitut (Inuktitut, Eastern Canadian), for example) acquire morphosyntactic structures in the earliest stages of acquisition. This is true but irrelevant. No inflected language preceded protolanguage, *ex hypothesis*; therefore, there were no morphosyntactic structures to be learned; the telegraphic speech produced before age 2 by children acquiring uninflected languages remains a highly probable approximation to prehuman protolanguage. Slobin also questioned evidence from trained ape productions, on the grounds that a trained ape "is sampling from an existing language" (2002: 378). This is untrue; most apes received examples from a made-up 'language' that can only be described as 'pidgin signed English.' Lexical items in this 'language' may have been modeled in structured utterances, but no syntactic structure was explicitly taught, and apes put the items together in ways that owed little to the models offered.

Hurford (2003) proposed that in earlier forms of language (and even in some modern human languages), there were no proper names. He used the philosophical argument that proper names imply certainty about the identity of their referent, and nonhuman creatures (presumably including hominids) cannot achieve such certainty, being easily fooled by imitations. But since words represent concepts rather than real-world entities, whether animals can be easily deceived about identities is irrelevant. If a nonhuman has the concept of an individual, that concept can be named, and no real-world misapplication of the name will affect its obvious utility. Directly contradicting Hurford is the fact (which he did not mention) that trained apes systematically distinguish between common and proper nouns, applying the latter uniquely to particular individuals with whom they regularly interact, even though the common/proper distinction was never explicitly taught.

Another limitation proposed for protolanguage is absence of verbs. According to Carstairs-McCarthy (1999), the fact that language as we know it distinguishes between sentences and noun phrases is surprising, and protolanguage could have consisted of nominalized phrases only. His claim is tied to a derivation of modern (sentential) syntax from the acoustic syllable, discussion of which would take us too far from the topic of this article. However, a verbless protolanguage seems intrinsically implausible. In modern languages, countless nouns are derived from verbs, and there are regular processes for such derivations. Conversely, vanishingly few verbs are derived from nouns, and these (e.g., *boycott*, *xerox*, *table* – as in *table a resolution*, etc.) are derived by no regular process and are almost always historically recent. This hardly suggests that nouns are evolutionarily older than verbs. Also, while most of the first words children learn are nouns, there are always a few verbs among them, and apes seem to learn verbs (with actions as referents) as easily as nouns (with entities as referents).

The most radical proposal regarding protolanguage is that the units it comprised were holophrastic rather than synthetic. This proposal, most thoroughly developed by Wray (2000, 2002), is implicit in the work of computer modelers and was explicitly endorsed by Arbib (2004) for different reasons. Wray's proposal drew support from those who believe

language is continuous with prelinguistic call systems. Units in these are best 'translated' as holophrases: 'I'm-higher-than-you-in-the-pecking-order,' 'Look-out-a-predator-is-approaching,' 'I-want-to-mate-with-you.' Wray proposed that protolanguage increased the number of such units until they imposed an excessive memory load. The holophrases were then decomposed on the basis of phonetic similarities.

Suppose, to quote Wray's own example (2000: 297), "if, besides *tebima* meaning *give that to her*, *kumapi* meant *share this with her*, then it might be concluded that *ma* had the meaning *female person + beneficiary*." This ignores the possibility that the syllable *ma* would also occur in many cases with no reference to either females or beneficiaries. The only alternative possibility is, if anything, still more damaging to Wray's case; if *ma* occurred only where female beneficiaries were involved, the holophrastic protolanguage would merely disguise a medium already fully synthetic. However, in the likelier case that *ma* sometimes occurred where a female + beneficiary reading was possible, but sometimes not, how would the hearer deal with the second set of cases?

Other problems involve the hidden assumption that a holophrase has only one synthetic equivalent (i.e., *kumapi* has to be interpreted by all speakers as equivalent to *share that with her* rather than to *let her take it*, minus the beneficiary reading, or *don't be so selfish*, minus both the beneficiary and feminine readings, either of which would be equally valid in most if not all contexts of use). Still further arguments against a holophrastic protolanguage can be found in Tallerman (2004).

Consequently there seems no compelling reason for adopting any alternative to a synthetic protolanguage with a categorially complete, if severely limited, vocabulary of items roughly equivalent to modern words but lacking both sophisticated phonology and consistent syntactic structure. However, the question of when protolanguage emerged merits a brief consideration, since any adequate account of it must eventually be integrated into the overall evolution of *Homo*. The wide range of estimates in the literature (from the australopithecine era to the emergence of our own species) suggests that at this point there are inadequate constraints to determine dates. Much depends, too, on the nature of the initial selective pressure. If this was scavenging (as suggested earlier in this article) the likeliest time of onset would be around 2 million years ago, placing the emergence of protolanguage at around the time of the speciation event that produced *Homo erectus*. Although there have been claims that australopithecines may have had some rudimentary form of language, this seems unlikely in view of their small brain sizes and the absence from the archaeological record of any artifacts they might have produced. On the other hand, delaying the emergence of protolanguage until our own species appeared suggests an unduly narrow window for the emergence of the entire suite of modern human language properties. Moreover, certain aspects of *Homo erectus*'s behavior, such as the use of fire, suggest (though it can be no more than a suggestion) that the latter species may have used some kind of linguistic medium. Thus, both the earliest and the latest dates suggested for protolanguage emergence can probably be dismissed, although any firm conclusions must await further investigation.

Clearly, at this stage of our knowledge, even the existence of protolanguage cannot be more than a plausible conjecture. Indeed, it is difficult to imagine what scientific evidence – short of cloning a *Homo erectus* from bone marrow DNA – would definitively indicate that protolanguage did exist. However, since protolanguage would have been sandwiched between some kind of primate call system and fully syntacticized modern human language, it is always possible that further study of animal communication and/or the syntax of natural languages will shed light on the initial stages. Pending such illumination, the notion of a protolanguage remains plausible, useful, and congruent with current knowledge, providing a sharper focus, as well as a productive stimulus, for thinking about the earliest stages of human language.

Imagine that you are asked to give a definition of the word *fruit*, such that, on the basis of your definition, a person would be able to use the word appropriately, that is, to refer to all and only the things that are called 'fruit.'

There are, broadly speaking, two ways in which you might approach the task. One approach would be to enquire what it is that all members of the fruit category have in common, in contrast to everything else that is 'not-fruit.' As a matter of fact, it turns out to be quite difficult to characterize the common essence of 'fruit.' For example, it would not do to define fruit as 'the seed-bearing part of a plant,' since the definition would encompass chestnuts, tomatoes, and pumpkins, which would not normally be described as fruit. You might try to improve the definition by including such aspects as the fact that the 'seeds' are surrounded by a fleshy part that is edible, in a raw, cooked, or dried state; that the edible part is 'usually sweet'; that it is 'often eaten as dessert'; and so on. Notice, though, that these latter aspects, though certainly typical of fruit, are by no means defining of the category. It would not be a contradiction to speak of a 'bitter fruit,' or of a 'poisonous' or 'inedible fruit.' Mention of these typical aspects does, however, raise the possibility of an alternative way to define the word, namely, in terms of its most typical exemplars. On this approach, apples and pears would be good examples of fruit, whereas tomatoes and olives would have marginal, or unclear, status within the category.

In a remarkable series of papers publishing during the mid-1970s, and summarized in Rosch (1978), the psychologist Eleanor Rosch presented experimental results that demonstrated that the categories designated by words such as *fruit* may indeed be understood in terms of 'good examples,' or 'prototypes,' whereby entities are assimilated to the category on the basis of their similarity to the prototype, rather than through their sharing of a set of common, defining features. The model was initially explored using the example of color words. The concept of 'red,' for example, would be understood, not as that segment of the color spectrum that is labeled 'red,' but in terms of a 'focal red,' a 'good example' of red, with other shades being called *red* to the extent that they are close to the focal color. The model was extended to other everyday words such as *weapon*, *vehicle*, *furniture*, *toy*, and *bird*. For example, we have a fairly clear

Imagine that you are asked to give a definition of the word *fruit*, such that, on the basis of your definition, a person would be able to use the word appropriately, that is, to refer to all and only the things that are called 'fruit.'

There are, broadly speaking, two ways in which you might approach the task. One approach would be to enquire what it is that all members of the fruit category have in common, in contrast to everything else that is 'not-fruit.' As a matter of fact, it turns out to be quite difficult to characterize the common essence of 'fruit.' For example, it would not do to define fruit as 'the seed-bearing part of a plant,' since the definition would encompass chestnuts, tomatoes, and pumpkins, which would not normally be described as fruit. You might try to improve the definition by including such aspects as the fact that the 'seeds' are surrounded by a fleshy part that is edible, in a raw, cooked, or dried state; that the edible part is 'usually sweet'; that it is 'often eaten as dessert'; and so on. Notice, though, that these latter aspects, though certainly typical of fruit, are by no means defining of the category. It would not be a contradiction to speak of a 'bitter fruit,' or of a 'poisonous' or 'inedible fruit.' Mention of these typical aspects does, however, raise the possibility of an alternative way to define the word, namely, in terms of its most typical exemplars. On this approach, apples and pears would be good examples of fruit, whereas tomatoes and olives would have marginal, or unclear, status within the category.

In a remarkable series of papers publishing during the mid-1970s, and summarized in Rosch (1978), the psychologist Eleanor Rosch presented experimental results that demonstrated that the categories designated by words such as *fruit* may indeed be understood in terms of 'good examples,' or 'prototypes,' whereby entities are assimilated to the category on the basis of their similarity to the prototype, rather than through their sharing of a set of common, defining features. The model was initially explored using the example of color words. The concept of 'red,' for example, would be understood, not as that segment of the color spectrum that is labeled 'red,' but in terms of a 'focal red,' a 'good example' of red, with other shades being called *red* to the extent that they are close to the focal color. The model was extended to other everyday words such as *weapon*, *vehicle*, *furniture*, *toy*, and *bird*. For example, we have a fairly clear

picture of what a prototypical bird looks like; it would be a small, flying songbird, such as a robin or a sparrow, rather than a turkey, ostrich, or penguin. If asked to draw a picture, or to form a mental image of 'a bird,' it is the prototypical bird that we would envisage.

Rosch and her colleagues developed the prototype concept on the basis of several kinds of data:

- when asked to judge entities according to how good an example they are of a category, people, on average, tend to agree on their rankings;
- when asked to give examples of a category, people tend to name prototypical examples first;
- when asked to judge the truth of a statement of the kind 'An X is a Y,' where X is a potential member of category Y, people respond faster to the extent that X is a more prototypical member of Y;
- When reasoning or drawing inferences about a category, people tend to refer to properties of prototypical exemplars, rather than to properties shared by all members of the category.

Rosch's work was popularized among linguists largely through the work of Lakoff (1987), Taylor (1989), and Geeraerts (1989). The prototype notion was not, however, completely new in linguistics. Independently of Rosch's work, Ross (1973) had argued that some nouns were 'nounier' than others, in that some exhibited the full range of noun-like properties and others exhibited fewer noun-like properties, whereas Labov (1973) had demonstrated prototype effects (though they were not so called) for the concepts 'cup,' 'bowl,' and 'vase.'

Not surprisingly, when taken up by linguists, the prototype notion was applied primarily to the study of word meaning – nouns in the first instance, but also words of other lexical categories, such as verbs and prepositions. Thus, Coleman and Kay (1981) showed that prototypical instances of 'tell a lie' involve making a statement (1) that is factually incorrect, (2) that is believed by the speaker to be factually incorrect, and (3) with the intention of deceiving the hearer. Statements that exemplify only two, or even only one, of these features were judged to be correspondingly less good examples of 'tell a lie.' The prototype concept has since been found to be useful in many other areas of linguistics, for example, in the study of meaning change, in the characterization of lexical and syntactic categories, and in phonology.

The notion of categorization by prototype has become a distinctive feature especially of cognitive semantics. There are, nevertheless, a number of contentious issues associated with the notion.

1. First, there is disagreement about what, exactly, the prototype is. Some have argued that it is an actual member of the category. Thus, we might say that the bird prototype **is** a robin. Others have argued for a more abstract characterization. For example, the bird prototype would consist of the conjunction of the typical features of birds – ability to fly, nest-building, etc. Alternatively, the prototype could represent the statistical average of the category members. Thus, the prototypical bird would be of average size, average predacity, etc. Yet another approach would be to claim that the prototype is the 'default' category member – the member that is activated in the absence of more specific information. Thus, on learning that a person has purchased 'furniture,' you would infer, in the absence of information to the contrary, that he or she had been buying tables, chairs, and beds, not clocks, lamps, and footstools.

2. Whereas 'prototype effects' (that is, speakers' judgments concerning how good an example an entity is of a category) are easy to elicit, it is less clear why certain members of a category should have this privileged status. One proposal is that prototypical instances are encountered more frequently or are culturally more salient. An alternative would be to adopt a more 'structuralist' approach, whereby the prototype maximizes the distinctiveness of a category vis-à-vis its neighboring, contrasting categories. Thus, the fruit prototype maximizes the distinctiveness of fruit vis-à-vis contrasting categories, such as 'vegetable' and 'nut,' whereas the bird prototype maximizes the distinctiveness of birds vis-à-vis land and sea creatures.

3. Prototype effects give internal structure to a category, in that some members are considered better examples of the category than others. This aspect of prototype structure is often referred to as degree of representativity, or goodness-of-example ratings. Sometimes – though not always – degree of representativity goes with fuzziness of category boundaries. Thus, 'red' merges, at its boundary, with 'orange' – there are boundary colors that are genuinely difficult to categorize as either red or orange. Similarly, there are receptacles that are ambiguous vis-à-vis the categories 'cup' and 'bowl,' or 'cup' and 'vase.' But prototype categories do not necessarily have fuzzy boundaries. A Pekinese may not be a prototypical dog, but it is a dog nonetheless, not a 'dog to a certain degree.' The category 'dog' does not merge with other categories at its boundaries. The need to distinguish goodness-of-example ratings from category fuzziness is illustrated by the example of categories such as 'odd number.' The category is well defined, yet some odd numbers, such as 3, are judged to be more representative of the category than others, such as 447 (Armstrong *et al.*, 1983).

4. Although knowledge of the category prototype may be an important aspect of knowing the meaning

of a word, word meaning cannot be equated with knowledge of the prototype. To know that robins are prototypical birds does not define the word *bird*, nor is this knowledge sufficient to guarantee appropriate usage of the word. A speaker needs to know how far, and in what ways, the category can be extended. It can be extended to encompass ostriches, penguins, and kiwis, but not to include bats, grasshoppers, and airplanes.

5. The nature and status of the prototype can vary according to the kind of word in question. For example, natural kind terms (that is, words that designate categories supposedly given by nature, such as *bird*, *mammal*, *gold*) presumably appeal to a defining essence (such as DNA, anatomical structure, chemical composition, as the case may be) that clearly circumscribes the category. Since the average language user may not be able to access the defining essence, appeal must be made to typical, observable, and stereotypical properties (such as yellow color in the case of gold or giving birth to live young in the case of mammals). Prototype effects can arise because such recognition procedures may be unreliable (think of the platypus – an egg-laying mammal). On the other hand, nominal kind terms (which are susceptible to an analytic definition), such as *vehicle* and *toy*, are liable to be much more fluid in their range of application and are likely to display both goodness-of-example effects and category fuzziness, not least because the terms used in the definitions (such as 'for children to play with' in the case of *toy*) may themselves exhibit prototype effects. It should, however, be borne in mind that even nominal kinds may have a clear-cut definition imposed on them, for example, by bureaucrats, lawmakers, and 'experts' in various fields. Thus, alongside the everyday understanding (with its prototype structure) of what constitutes an 'adult,' there exists the bureaucratic definition of a person above a specific age (in many countries: 18).

6. The prototype notion has been extended and applied to the analysis of polysemy. Irrespective of whether *bird* is used in reference to a robin or an ostrich, we should probably want to say that *bird* has the same sense in both cases; the fact that *bird* can be applied to different kinds of creatures does not in itself entail that the word is polysemous. But if you speak of a person as a 'rare bird,' or when (in what is now perhaps somewhat dated British slang) males refer to attractive young females as 'birds,' we should probably want to say that *bird* is being used in different senses, i.e., that the word is polysemous. For a polysemous word, one sense can often be regarded as 'central,' from which the others are derived, e.g., by processes of metaphor or metonymy. Although one sense may be regarded as the 'prototype,' it must be remembered that each of the senses of a polysemous word is itself liable to have a prototype structure. The application of the prototype notion to polysemous words is, however, complicated by the fact that it may be difficult to determine which of the senses is in fact 'the prototype.' For example, is the 'static' sense of *over*, exemplified in *The lamp hangs over the table*, the basic sense, or should we accord this status to the dynamic sense, exemplified by *The cow jumped over the moon*?

Despite these problematic aspects, the prototype concept continues to play an important role in linguistic analysis, especially in the study of word meaning, not least because it offers an alternative to the view that categories must always be defined in terms of a set of necessary and sufficient conditions for category membership. For many – perhaps, even for most – words in common usage, a definition in terms of a 'core' meaning, instantiated in each of a word's uses, simply does not work.

Proxemics

M Danesi, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

An intrinsic feature of social contact rituals involves the maintenance of specific zones that people perceive as meaningful. The study of such zones now falls under the rubric of 'proxemics,' a word derived from the Latin *proximus* 'near' and the suffix *-emics*, in analogy with such terms as 'phonemics' and 'morphemics' in linguistics. The term thus betrays a connection to linguistic notions as the basis for studying and describing interpersonal zones, which involve knowing how close to stand to someone during social interaction on the basis of age, degree of familiarity, gender, etc.

Proxemics was founded by the American anthropologist Edward Twitchell Hall (1914–) in the late 1950s and early 1960s (1959, 1963a, 1963b) after his systematic study during World War II, when he served in the US Army in Europe and the Philippines, of the zones people maintain. Hall came to realize that failures in intercultural communication arose typically from unconsciously coded differences in the ways that members of different cultures perceived interpersonal distances and in the ways they acted within them. Hall developed proxemic methodology throughout the 1960s and 1970s (1959, 1963a, 1963b, 1964, 1966, 1968, 1974, 1976, 1983). Using American culture as his test case, he showed how it is possible to measure and assess critical interpersonal zones.

In 1963, Hall defined proxemics broadly as "the study of how man unconsciously structures microspace – the distance between men in conduct of daily transactions, the organization of space in his houses and buildings, and ultimately the layout of his towns" (Hall, 1963b: 1003). A year later, he limited its purview somewhat to "the study of the ways in which man gains knowledge of the content of other men's minds through judgments of behavior patterns associated with varying degrees of proximity to them" (Hall, 1964: 41), which he restricted further a few years later to the study of "the interrelated observations and theories of man's use of space as a specialized elaboration of culture" (Hall, 1966: 1).

Hall's proposal to study the distances people maintain between each other has led to a large body of data on this aspect of social behavior. Most of the data shows that interpersonal zones are measurable with statistical accuracy, varying predictably and systematically according to age, gender, and other social variables (e.g., Segaud, 1973; Loof, 1976; Pinxten *et al.*, 1983; and Watson and Anderson, 1987). Today, proxemics is a robust area of research pursued by all kinds of social scientists (Mehrabian, 1969, 1972, 1976; Sundstrom and Altman, 1976; Canter, 1977; Moles and Rohmer, 1978; Harper *et al.*, 1978; Argyle, 1988; Lawrence and Low, 1990; Niemeir *et al.*, 1998). Hall did not explicitly use semiotic notions to study proxemic behavior, but his whole outlook and framework are, *de facto*, semiotic in nature. The inclusion of proxemics as a branch of nonverbal semiotics started with Eco (1968: 344–349) and Watson (1970, 1974).

The Proxemic Paradigm

The study of proxemic behavior consists of three general components (Hall, 1966; Watson, 1974): (1) spatial dimensions, (2) levels of interpretation of these dimensions, and (3) physical features of spaces. Each one consists of three subcomponents, called 'micro,' 'meso,' and 'macro.' 'Microspace' is the immediate physical environment constituting a sphere of privacy, 'mesospace' is the next zone that is within the person's reach but that falls outside the privacy sphere, and 'macrospace' refers to the larger social spheres, including settlements, cities, and beyond. The three levels of interpretation are called 'infra,' 'pre,' and 'micro.' The infra level is rooted in our 'biological past' (Hall, 1966: 95), involving our innate sense of territoriality as the guiding force in establishing boundaries. The pre level is rooted instead in inborn sensory (tactile, visual, etc.) perceptions of space that crystallize over time into culture-specific codings of space. Those are interpreted at a micro level. The three physical features are called 'fixed,' 'semi-fixed,' and 'dynamic.' Fixed features include such things as walls and territorial boundaries, semi-fixed features are mobile elements such as curtains and screens, and dynamic features are those such as vehicles that can vary in certain spaces.

Territoriality

Animals reside in territories that they have appropriated as their own, or in some negotiated arrangement with other animals, so that they can procure shelter, alimentation, and habitation. This applies to humans as well. But, unlike other species, humans also manifest a compulsion to ascribe social meanings to the territories in which they are located as groups.

Biologists define 'territoriality' as: (1) an innate survival mechanism that allows an animal to gain access to, and defend control of, critical resources such as food and nesting sites that are found in certain habitats, and (2) the instinctive need of an animal to procure a safe boundary around itself. The Austrian zoologist Konrad Lorenz (1903–1989) was among the first scientists to identify and document the patterns animals display in marking territoriality. Such patterns, he proposed, were an important part of an animal's repertory of survival strategies, as critical in evolutionary terms as its physiological endowments. Lorenz also suggested that human aggression and warfare were explainable as residual territoriality impulses – a controversial theory that gained widespread popularity through a best-selling book written in 1966 by Robert Ardrey, generating a heated debate in academia and society at large on the nature and origin of human aggression. The notion of territoriality in human life continues to receive much support because of its intuitive appeal – intrusions into appropriated territories (e.g., into one's home, car, etc.) are indeed perceived typically as signals of aggression, in the same way that a cat, for example, would likely react aggressively to another cat intruding upon the boundaries it has proclaimed by urination.

The main implication to be derived from the work on territoriality is the fact that we all need to maintain a boundary around ourselves for our protection and sanity. Hall was among the first to see the relevant social implications of this, and thus to investigate the proxemic patterns people establish and maintain between each other when interacting. He noted that these could be measured very accurately, allowing for predictable statistical variation, and that the dimensions varied from culture to culture. In North American culture, Hall found that a distance of under six inches between two people was perceived as an 'intimate' distance; while a distance at from 1.5 to 4 feet was the minimum one perceived to be a safe distance. Intruding upon the limits set by this boundary causes considerable discomfort. For example, if a stranger were to talk at a distance of only several inches away from someone, he or she would be considered rude or even aggressive. If the 'safe' distance were breached by some acquaintance, on the other hand, it would be interpreted as a sexual advance.

Factors

Once the levels and features are determined, Hall posits eight factors as significant in proxemic behavior. These are:

1. Postural-sex identifiers (standing vs. sitting, male vs. female)
2. Sociofugal-sociopetal orientation factors (face-to-face, back-to-back)
3. Kinesthetic factors (distances of body parts, from reaching to contact)
4. Touching factors (from caressing and holding to no contact)
5. Visual factors (gazing, looking away, looking directly into the eyes)
6. Thermal factors (whether radiated heat is detected or not)
7. Olfaction factors (detection of odor or breath)
8. Vocal factors (loudness of voice, tone of voice).

As in linguistics, the idea of scientifically studying interpersonal zones involves two levels: (1) the actual physical description of the factors used *in situ*, known as 'proxetic' description (in analogy with 'phonetic' description), and (2) the analysis of how these relate to each other structurally, known as 'proxemic' analysis (in analogy with 'phonemic' analysis). The relevant 'proxemes' are determined by comparing them and contrasting them to each other within the broader framework of an interaction.

Interpersonal Zones

Overall, Hall found that there are four main types of zones: 'intimate,' 'personal,' 'social,' and 'public.' Hall further subdivided these into 'far' and 'close' phases. For American culture, he found these to be as follows: (1) intimate distance (0 in.–18 in.), (2) personal distance (1.5 ft.–4 ft.), (3) social distance (4 ft.–12 ft.), and (4) public distance (12 ft. and beyond).

At intimate distance, all the senses are activated and the presence of the other person or persons is unmistakable. The close phase (0 in.–6 in.) is an emotionally charged zone reserved for love-making, comforting, and protecting; the far phase (6 in.–18 in.) is the zone in which family members and close friends interact. Touch is frequent at both phases of intimate distance. Personal distance is the minimum comfortable distance between non-touching individuals. In the close phase (1.5 ft.–2.5 ft.), one can grasp the other by extending the arms. The far phase (2.5 ft.–4 ft.) is defined as anywhere from one

arm's length to the distance required for both individuals to touch hands. Beyond this distance the two must move to make contact (e.g., to shake hands). In essence, this zone constitutes a small protective space. Social distance is considered non-involving and non-threatening by most individuals. The close phase (4 ft.–7 ft.) is typical of impersonal transactions and casual social gatherings. Formal social discourse and transactions are characteristic of the far phase (7 ft.–12 ft.). This is the minimum distance at which one could go about one's business without seeming rude to others. Public distance is the distance at which one can take either evasive or defensive action if physically threatened. Hall noticed that people tend to keep at this distance from important public figures or from anyone participating at a public function. Discourse at this distance tends to be highly structured and formalized (lectures, speeches, etc.).

Conclusion

Semiotically, zones are signs that are governed by 'body codes' that also regulate bodily orientation (*see* **Kinesics**). If someone is standing up at the front of an audience, he or she is perceived as more important than those sitting down. Speeches, lectures, classes, musical performances, etc. are oriented in this way. Officials, managers, directors, etc. sit behind a desk to convey importance and superiority. Only their superiors can walk behind the desk to talk to them. To show 'friendliness,' the person behind the desk will have to come out and sit with his or her interlocutor in a different part of the room.

The study of such proxemic behavior has made it obvious that physical environments and the features within them are perceived as signifying structures. This is the reason why proxemics is now considered to be largely a branch or subfield of semiotics and is included in basic textbooks in the field (e.g., Nöth, 1990; Danesi and Perron, 1999).

Proximatives

T Kuteva, Henrich-Heine Universitat, Dusseldorf, Germany

The proximative is a grammatical verbal category meaning a temporal phase located close before the initial boundary of the situation described. This category does not, as a rule, figure in standard grammatical descriptions. Where the expression of an action imminent to happen (the proximative) is mentioned at all, it is usually considered a peripheral, modal use of the relevant construction. In the languages where the proximative happens to be recognized as a particular verb meaning regularly linked to a particular linguistic structure, it is considered an idiosyncratic verb construction rather than a grammatical category in its own right. An exception to the common practice is Comrie (1976: 64–65), who has noted the proximative and has moreover acknowledged that the form in question expresses a grammatical distinction. The first work in which a case was built for the cross-linguistic validity of the proximative as a full-fledged grammatical category is Heine (1992).

Note that many languages have only lexical means to express the meaning of an action imminent to happen. Spanish, for instance, has the metaphorical expression *estar a punto de* 'be on the point of' for the proximative notion:

(1) Spanish
El concierto esta a punto de empezar.
the concert be.3SG.PRES at point of start.INF
'The concert is about to begin.'

In the cases where the proximative is a grammaticalized category, the most frequent historical sources for the proximative structure involve constructions with the lexemes *want*, *love*, *come to*, *near* (Romaine, 1999; Heine and Kuteva, 2002):

(2) Swahili (Bantu, Niger-Congo)

(2a) ngoma i- na- taka ku- pasuka.
drum C9- PRES- want INF- split
'the drum is about to split'

(2b) mvua i- li- taka ku- nyesha.
rain it- PAST- want INF- rain
'it was about to rain' (Heine, 1994)

In past contexts, the proximative comes close to the avertive (meaning 'was on the verge of V-ing but did not V'), which was also identified as a category in its own right only very recently (Kuteva, 1998; Heine and Kuteva, 2002). There are both semantic and morphosyntactic reasons, however, for keeping these two categories apart. Semantically, the proximative is a purely aspectual category (involving the notion of imminence), whereas the avertive is an aspectual-temporal-modal category (involving the notions of imminence, pastness, and counterfactuality at the same time). Morphosyntactically, whereas the proximative can be used in both past and nonpast contexts, the avertive can only be used in past contexts.

Psychoanalysis and Language

The Other

Language is central in psychoanalysis inasmuch as free association is the main rule in the treatment of neurosis, and psychosis is considered a particular disease of language. Hence, Sigmund Freud (1856–1939) underlined the importance of language in his work on dreams (*Die Traumdeutung*), on the psychopathology of everyday life (*Zur Psychopathologie des Alltagslebens*), and on the joke (*Der Witz und seine Beziehung zum Unbewussten*). As these works stress, the dimension of truth is not in the spoken word, but exists on another scene, as Freud has shown us, principally through his occupation with the joke. It is the other scene which gives sense to the joke, because this sense does not exist in the joke's spoken words.

The truth is unspoken. This is particularly the case in the famous 'slip of the tongue', which gives access to an unknown knowledge located on another scene, or in 'the Other', as the French psychoanalyst Jacques Lacan (1901-1980) later was to name it. The truth exists at the Other's location; this location is another name not only for the unconscious, but also for the intersubjectivity that determinates it, as the case of the joke underlines: the effect of the joke cannot be separated from the other(s) listening to it. This also means that language cannot be understood as something inhabiting, or placed in, the brain, as cognitive theories of language or a cognitive therapy presume it to be. Nor is it regulated by these theories' so-called 'mental schemes', but by the relationship between the subject and the Other. This Other is never a concrete instance, even though it may be localized by, e.g., identifying linguistic codes, or by listening to the subject's speech. While every subject is determined by its being localized, the Other remains outside of it, not being a subject.

It follows that the subject is divided between what it says, and the way its words are addressed. This can be seen in the difference between an utterance and its enunciation, as illustrated by the famous sentence: "I lie," whose normal interpretation underlines that, inasmuch as the I is lying ("I lie"), the sentence itself must be false, which means that the I cannot tell the truth regarding its own lying and that consequently, the sentence either is pure nonsense or produces an unsolvable paradox. However, it is possible to make a distinction between the *utterance* in which the I is lying, and its *enunciation*, as coming from another place (the Other's), where the I is telling the truth. The former I is the I of the utterance, while the latter is the I of the enunciation; it is a linguistic element called a 'shifter' (*see* **Deixis and Anaphora: Pragmatic Approaches**), but here understood in a psychoanalytic, not a strictly linguistic framework.

The same can be seen in the technique of free association. In the analysis, the subject (in this case, the neurotic subject) is requested to say everything that comes to mind, even though it may seem unessential or even stupid. Through free association, the subject is supposed to be able to escape from the superego and its censorship. However, the associations are not really free, because they are determined by the subject's unconscious (that is, by the other scene), or, in Lacanian terms, by the Other.

The truth of the subject's words (or signifiers, as Lacan says), comes from the Other, which is both included in, and at the same time outside of, the enunciated signifiers. Hence, the subject receives its own message from the Other, but of course not directly the way it is said, but in a form that both precedes and follows the message. Lacan puts it this way: the subject receives its own message in an opposite form from the Other (cf. Lacan, 1955–1956: 47).

Among other reasons, this is also why Lacan stresses that the words which the subject uses must not be understood as elements of meaning, but as signifiers. If there is a meaning in those elements, it is constituted as such only after they have been enunciated. The importance of the signifiers is not necessarily to be found in their meaning (virtual or otherwise), but in the fact that one signifier represents the subject to another signifier (one of Lacan's canonical statements; see, for example, Lacan, 1964: 180f). Sometimes, a chain of signifiers can be connected to a special signifier and thereby create a particular signification. Such a connection is also indicated in Lacan's notion of the *point de capiton* (cf. below); as we will see, the main importance of the subject's work is not in the dimension of meaning, but in the desire.

Desire, Metonymy, and Metaphor

The notion that one signifier represents the subject to another signifier stresses the fact that the subject in language constitutes a kind of hinge in the signifier chain between two or more of its signifiers. By himself, the subject is empty, because his very act consists in putting signifiers together, starting from a place where there is nothing, viz., the empty space(s) between the first, second, third, ... etc., signifier. This act does not lend any substance to the subject; it only provides him with a position that has no

content. However, the very act of putting the signifiers together is also what Lacan defines as *desire*. Desire is not only the movement in a chain of signifiers produced by the subject: the very movement is established by the subject's desire. The desire thus represents a 'sliding' of the signifiers; the subject resides in the interval from which this sliding takes place.

Lacan points out two fundamental functions of the signifiers' work: to wit, metonymy and metaphor (cf. Lacan, 1957). The names for both these functions have their origins in classical rhetoric, (*see* **Rhetoric, Classical**) but Lacan restricts the first – metonymy– to cover the displacement in the chain of signifiers, where this displacement is determined by the subject's desire. In other words, desire itself is defined by the metonymic displacement in the signifiers (*see* **Metonymy**). Regarding the second function, metaphor, Lacan, in accordance with a certain understanding of classical rhetoric, defines this function as a replacement – more precisely as a replacement of one signifier by another (*see* **Metaphor: Psychological Aspects**). However, the replaced signifier does not disappear forever, but continues to exist in the unconscious or in the preconscious. The analysis may reveal such replaced signifiers in, e.g., the subject's free associations.

This way of considering metonymy and metaphor also provides an interpretation of Freud's thoughts about displacement and condensation in dreams (Freud, 1900). According to Freud, the manifest dream has a latent level, which is censured by the subject's superego. The subject therefore has no direct access to the latent elements of the dream, but can unfold these in the analysis by first telling the dream and then associating about it. Between the latent and manifest levels of the dream, Freud locates different functions of a linguistic kind which allow the unconscious to make its way up toward the conscious, thus avoiding the superego's censorship. One of these functions is *displacement*: a latent dream element can be displaced to another, which the censorship then allows to be manifested. Thus, a sexual wish with regard to someone who is not allowed by the superego to function as a sexual object can be displaced toward a person who is acceptable to the superego. Lacan's term for such a displacement is precisely 'metonymy' (Lacan does not limit the use of this notion to dreams, but also employs it to characterize desire, as we saw above).

Another function of the dream, as identified by Freud, is *condensation*. By this, Freud means that one manifest dream element can be seen as a 'condensation' of different, latent dream elements. For example, the image of a given person in a dream can consist of different smaller images of other persons. The person in question is thus condensed out of several other persons. Such a condensation can also be seen as a meeting of different chains of signifiers, where the 'knot' of the meeting place constitutes a particular metaphor.

The importance of the dream work lies neither in the latent nor in the manifest dreams taken by themselves, but in the work that goes on between the two levels, in particular with regard to wishes, which show up in the 'cracks' between the dream levels. These wishes follow the logic of language when they try to pass by the censorship, *in casu*: the logic of metonymy and metaphor. (Lacan sees these wishes as 'desire', as already noted).

The idea that dreams act according to the logic of language is in accordance with Freud's saying that the dream is the 'royal road' to the unconscious. But Lacan goes a step further, and says that the unconscious is structured as a language (1957–1958: 474). Lacan conceives of metaphor as another way of defining certain dream mechanisms; more generally, metaphorical mechanisms are not limited to dreams, but encapsulate the entire linguistic process, as it determines the subject's position in language.

Even though this conception is similar to an understanding of metaphors current in classical rhetoric, the emphasis for Lacan is on the way the metaphoric act orients the subject and its desire. The metaphor not only replaces another signifier, but also stops the otherwise infinite chain of signifiers. In this sense, the metaphor weights a certain orientation of the desire, enabling the signification connected to the chain. It constitutes a kind of 'This is it' experience or, in Lacan's words, a *point de capiton* (lit.: 'one of the buttons that keep the fabric of the couch together'); it needs scarcely to be said that the discovery of such a button often will lead to rather big surprises (Lacan, 1955–1956: 303).

Take for example the case of the patient who, having talked for a long time about how great her father is and having used all kinds of superlatives to confirm his greatness, suddenly exclaims: "He is monstrous." The word 'monstrous' gives a whole new meaning to the earlier signifiers in the chain. Of course, the word 'monstrous' can be taken as a merely replacing the noun phrase 'very kind' (as in "He is very kind"), and thereby add weight to the father's kindness. However, 'monstrous' also says something more: either the father is too 'kind', and for this reason has not been able to put any bounds on the role played by to the near-almighty mother in the patient's life, or the subject suspects that behind all this kindness, something dangerous is lurking: "My father is very kind, but perhaps, underneath

all his kindness, he is rather terrifying and aggressive." Such a reorientation of the patient's attitude to the father (or: the parents) can bring in a new perspective.

Psychosis

In the case of psychosis, which is one of the main areas of work in Lacanian psychoanalysis, metaphor has a particular role to play. Often, the psychotic subject suffers from a metonymically determined and displaced desire; being situated in a language environment (the signifier chain) where there are neither boundaries nor borders, his ability to create metaphoric supports or dividers is severely reduced. To use Lacan's picture: there are no real *points de capiton* in the psychotic subject's language. Being overwhelmed by language, he cannot locate any space in between two or more of the signifiers, and consequently cannot reach the other to communicate. The intervals between the first, second, third, etc., signifiers seem to disappear, and this effaces the position of the subject. Instead of being a communicative tool, language acts like a kind of infinite metonymy, which not only disables the subject in its attempt to communicate with the other, but also deprives it of its possible orientation in desire.

The psychotic subject does not inhabit the language, but is inhabited *by* language. Or, to use a famous sentence from the world of literature, one could describe the psychotic linguistic experience with the words: "Language is a virus from outer space" (W. S. Burroughs). One of the main therapeutic potentials in working with a psychotic subject is hence to establish metaphors providing weight and orientation to the desire, thereby also setting some limits to the overwhelming language.

For the psychotic subject, the situation is particularly difficult, being determined by the conditions of entrance (or, rather, the lack of entrance) to language. Instead of accepting language (cf. the Freudian *Bejahung*), the subject has foreclosed it, as Lacan remarks (1959). The place of psychosis relative to language has never been well established, which means that it assumes the characteristics of a language 'disease', the psychotic subject not being able to express itself in language. Hence, it is common to see, in some cases of psychosis, that the so-called 'shifters' (see above), for example, I/you, now/then, or here/there, do not function, which often results in the psychotic subject's feeling alone with his speech. The subject is not oriented in the space and time of the discourse, nor as to his linguistic relationship to the other. The person is not able to delimit what is outside the language, namely the *jouissance* (see below). Freud also uses the term 'primal repression' to describe this failed access to language by which the primal, limiting repression says No to the limitless *jouissance* (cf. Freud's notion of *Verdrängung*).

Jouissance

When we talk about desire and language, we necessarily must stress yet another aspect connected to these concepts. Even though the (neurotic) subject is constituted in and by language (as this is manifested through desire, the signifier chain, and thought), its placement in, and confinement through, language prevents it from having a direct connection to its body. This can be seen by a particular, psychoanalytic interpretation of Descartes' formula *Cogito, ergo sum*: "I think, therefore I am." For psychoanalysts, the comma between "I think" and "therefore I am" is rather important, as it underlines the division between being and language: the place where the subject thinks is also the place where it (in particular its body) is not. The signifiers can perhaps name the body, but they are not the body. The name and the named are not the same. By its entrance into language, the subject leaves a part of itself outside itself: language does not comprise its entire being (this is true for all language users, but of course the 'entrance' does not function in the same way in the case of psychosis; cf. above). Thought and speech are only a part of the human's being, the rest of it falls outside language.

This also means that experiences connected to the body can overwhelm the subject. Freud's ideas about sexuality and its problematic status in our lives underscore this. Sexuality causes problems because it disturbs the subject's thinking and desire in language. This is also why Freud caused such an uproar by talking about sexual problems in Vienna more than a century ago. However, the uproar was not so much due to its location in time and place, which was still marked by the Victorian moral code and its strong repression of sexuality, as to the place of sexuality within, and its relationship to, the subject's own body.

The thought/body division, as manifested in the Cartesian comma, marks the fact that the subject *is* not its body, but *has* it. Having it, the subject can also lose it, or be alienated from it by the subject's very act of being constituted in language. The existence of the subject in language has the form of an alienation, as it is merely assigned a place between two signifiers, which it cannot use as instruments as it pleases, but only put together according to a certain logic of language. Furthermore, this logic does not include the body, which by definition is placed outside language. Hence, an early childhood experience of sexuality connected to the body manifests itself as something

alien to it, as it cannot be properly worded, thus making the sexual experience essentially strange and traumatic for the child as subject.

Sexuality is not limited to the genital organs and the erogenous zones connected to the drives (anus, mouth, ear, and eye), though this is often thought to be the case. This is why Lacan uses the term *jouissance* ('enjoyment') to define this strange feeling concerning the body, the drives, genital sexuality, and other bodily functions. The subject is not responsible for the *jouissance*, but for its response to it. In itself, a *jouissance* touching the body, but without making the connection to language, is traumatic. A *jouissance* happening outside the reach of language cannot be controlled; the lack of response to *jouissance* undermines the subject's linguistic place, and naturally the subject tries to defend itself against this trauma.

The Neurotic Defense

Neurosis can be seen as a rather successful defense against the trauma outlined above, as it precisely develops symptoms by way of language. This is clearly seen in the case of hysterical symptoms such as frigidity, vaginal problems, or cases of temporary paralysis having no bodily or neurobiological causes. In paralysis, the traumatic experience of the body in its repressed *jouissance* is displaced (cf. metonymy), or converted to a part of the body that is different from the original part which gave rise to the *jouissance*. Hence, the bodily hysterical symptom is due to, and constituted by, a compromise between the repressed and displaced *jouissance* and language.

The paralyzed, hysterical subject is prone to think: "I do not want to have this strange sexual feeling, let me get rid of it." However, the repression does not succeed (it never does!); instead, it manifests itself in the paralysis, which contains two different, contradictory aspects: one is to get rid of the enjoying body, and the other the impossibility of doing this. In the case of hysteria, the repression of enjoyment connected to the erogenous zone is displaced to another part of the body, which then becomes erogenous, even though it was not originally. The subject protects itself against its own disappearance; the anxiety about this is caused by the bodily feeling that denies the subject its place in language. The same happens in cases of epilepsy, or in hysteria-related fainting spells, in which the sexual feeling is displaced in a way that includes the whole body. Both epilepsy and fainting mark the return of the *jouissance* that formerly was connected to particular parts of the body (the sexual or erogenic zones): while the former enjoyment was located in a single part of the body, these two phenomena affect the whole body. While unconsciously trying to defend itself against bodily enjoyment via these two phenomena, the subject only 'succeeds' in this effort by having itself (at least momentarily) wiped out by another *jouissance*, taking possession of the whole body.

In cases of obsession, by contrast, the neurotic defense attempts to get rid of *jouissance* by excluding the very body. The obsessional (often socially isolated) person is constantly suffering from worries; such thoughts, while they prevent *jouissance* from happening, also, but unintentionally, provide the subject with a special language-based enjoyment. Often the patient does not realize that there is no way to control the body, to preempt its functions, or to keep it from manifesting itself. This becomes clear when we look at the subject's relationship to the bodily function of excreting. The feces can only go one way, which shows the limits of bodily control. No wonder, then, that the obsessional subject often has problems having to do with the anal drive.

However, in neurosis there exists – in contrast with the often defenseless psychotic situation – a specific, linguistically determined defense mechanism aimed at limiting *jouissance*; these mechanisms are borne out by what happens in hysteria and obsession. In hysteria, by way of language, the sexual experience is converted to another bodily symptom, while in obsession, it is repressed (or effectively hidden) by the mind's massive control of the body: truly 'mind over matter'.

The Psychotic Defense

That said, desire in neurosis also functions as a kind of defense against the unlimited *jouissance*. Contrary to what is the case in psychosis, the metonymic 'slide' in language that we have defined earlier allows the neurotic subject to escape the disturbing *jouissance*. The psychotic subject, on account of its problematic placing itself in language, does not have the same linguistic possibilities of defending itself against *jouissance*. Being itself uncontrolled and without bounds, *jouissance*, whenever it occurs, seems to throw the subject off balance, making it lose its self-control and its bearings. In paranoia, one of the main forms of psychosis, this is often manifested as the subject imagining being forced by another subject to undergo *jouissance*, and thereby destroying it. For example, this other subject may be a man (or even God), who wants the male subject to change his sex, to become a woman, so the man (or God) can have intercourse with it. The psychotic subject is forced by this particular other to become a woman, which of course has some very terrible consequences for the subject. In

this way, approaching the sexual act or other kinds of *jouissance* may eventually lead to the destruction of the subject; alternatively the other may be interpreted as a persecuting and highly dangerous man (or, as the case may be, God).

In schizophrenia, the body is fragmented and non-coordinated. While in normal cases, the language allows the subject to interpret and perceive its body as a more or less coordinated whole (despite its necessary and unavoidable alienation through language), the schizophrenic subject experiences the body as being dissolved upon its being invaded by the unlimited *jouissance*. A patient once told me how her eyes moved to the back of her head, or how she became transparent, or disappeared, when too many people in her environment looked at her. Nor is she able to recognize herself in photos. She is not able to regard her body as a whole body, nor does she recognize the image of her own body. Another patient told me about a dream in which he was making love to the [singer] Madonna, when suddenly, her sex changed from vagina to penis and his own penis got stuck in the middle. While the paranoiac subject mainly places the *jouissance* in the relationship to a persecuting other, the schizophrenic locates it in its own, dissolved body.

The Real

The relationship between language and psychoanalysis cannot be limited to language or speech alone just because the latter two stand in a special relationship to the body and enjoyment. Psychoanalysis works in and through language; nevertheless, it also concerns the *jouissance* that happens outside of language. Not only that, but the work of psychoanalysis in and through language precisely addresses that which escapes language. Lacan has a specific name for this: the *Real*. The Real is not the designated reality, for example a certain thing, as it is referred to through language; it is that which language cannot possibly grasp. This includes the body, which can be named, but cannot be reduced to signifiers or names. The Real concerns the limits of language.

Even though language, from a purely empirical point of view, may seem to be unlimited (we can always say something more or something new), language does contain a limit: language cannot grasp itself. This fact can only be approached from a logical point of view (actually, an instance of Russell's famous paradox, by which no set can be a member of itself).

Let's assume we have a set X, whose members are the elements of a language: $x_1, x_2, \ldots, x_n$. Let's further assume a relation of 'grasping', G; G(y,z) is read as 'y grasps z'. (Intuitively, this may be understood as 'y reflects on z, makes a statement about z', and so on). If any linguistic element xi is to grasp X, it cannot be a part of X, but must be understood as an xi′, grasping X: G(xi′,X). But since xi′ is also a linguistic element, it must be part of X, thereby creating a new set, X′, containing the original elements of X, plus xi′. Now if we want to grasp this new set X′, we must posit a third element, xi″, and so on *ad infinitum*. Every time we get a term which is meant to grasp the language, this term is not included in the language itself: no language or signifier can grasp itself. From a psychoanalytic point of view, this impossibility defines the Real, in that it constitutes the limits of language.

For the subject, this limit shows up in the bodily *jouissance*, whereas the act of putting signifiers together is a way to avoid the Real: it is also, as we have seen, an act determined by desire. Enjoyment, or *jouissance*, is the effect that accompanies the subject's approaching the Real; in contrast, anxiety is what overcomes the subject upon its return to language. This can be illustrated by the case of the drunken subject who gets enjoyment from being drunk, but is struck by anxiety the day after. The same can happen to a schizophrenic subject, who can enjoy sexual intercourse, but then suddenly is struck by anxiety upon feeling his/her body fall apart. These two examples underline the importance in psychoanalysis of working with language, and with the way it limits itself in the subject's relationship to the Real.

Discourse

Lacan further delineates the relationship between language and the Real in his theory of the four discourses (Lacan, 1969–1970). Here, it is only possible to present certain aspects connected to the first of these four, the master discourse (the three others being the hysterical discourse, the analytic discourse, and the discourse of the university). The master discourse contains four elements: S1 (the first signifier, also called the master signifier); S2 (the second signifier, also called knowledge); $ (the divided subject); and object *a* (which will be defined below). The relationship between these four elements is constituted by Lacan's well-known definition: the signifier (S1) represents the subject ($) to another signifier (S2); in Lacan's notation:

$$\frac{S1}{\$} \rightarrow \underline{S2}$$

The first signifier, S1, opens the discourse, while at the same time constituting the discourse as relatively closed (for instance, one does not use the same expressions about the body in medical and in obscene

discourse). In itself, S1 is empty; its function is to unlock a linguistic field (the discourse) while at the same time closing it off to what is outside the field. S1 creates an opening toward a discourse, but it is also inconsistent and ignorant, because its function is limited and its knowledge exists only in S2. However, by fulfilling this limited function, S1 makes it possible for the subject to find the other signifier (S2), which then establishes the knowledge in the discourse. A military order – 'Attack' – constitutes such an S1; the soldiers react to this first signifier, as they must, in accordance with the possible knowledge of the attack situation that is available in the second signifier. The same applies to a great number of contexts that similarly depend on a master-signifier; among these is the unconscious which, according to Lacan, by and large is organized on the pattern of this master discourse.

However, *jouissance*, too, plays a role in the discourse inasmuch as this is constituted as a linguistic field, guaranteed, but also limited by S1: S1's function is to restrict what otherwise could lead to unlimited bodily *jouissance*. While constituting the linguistic field, S1 at the same time constitutes (implicit and explicit) parts of the discourse falling outside of the field (as we have seen in our discussion of *jouissance* and the Real). Such is for example the case for discourse in the classroom, where the students are not supposed to fight while being taught.

Here, the language of the discourse does not cover all aspects of the linguistic acts. A person may say either too little or too much (the latter being the case in the famous 'slip of the tongue'). And even in the classroom, where for example fighting during classes is forbidden, students can always make drawings on their papers, rather than paying attention to the teacher, or whisper to their friends.

The master discourse – here the lesson – leaves open the possibility of an enjoyment which is not unlimited (as is the fighting in the schoolyard, or the bodily *jouissance* outside of the discourse). This kind of enjoyment, which happens within, and stems from the discourse, is called the 'more-to-enjoy' (or 'surplus enjoyment') by Lacan; he also names it 'object *a*'. Object ('little') *a* is a surplus produced by the discourse, even though it falls outside the relationship between S1 and S2. In Lacan's notation, it looks like this:

$$\frac{S1}{\$} \rightarrow \frac{S2}{a}$$

As we see, S1, the master signifier, and S2 are placed above the dividing line (hence the name 'master discourse'), while the subject and the object *a* are placed under the line, thus symbolizing the dividing spread of the signifying process in metaphor and metonymy, and the ban on *jouissance*.

In this discourse, furthermore, the master signifier is located at the place of the agent. The agent addresses itself to another, who is to produce knowledge (cf. the military order 'attack', given to the soldiers by the officer). The discursive roles (or 'places') are named, respectively:

$$\frac{\text{The agent}}{\text{The truth}} \rightarrow \frac{\text{the other}}{\text{the product}}$$

The dividing line signals a barrier of exclusion between the upper and lower levels, meaning that the agent, when uttering S1, does not know the subject below the line (*$*), who is included in the discourse. In our example, the officer giving orders does not worry about the subject underneath the line: his own unconscious; neither is he worried about the other's (the soldier's): the latter simply obeys orders by producing the knowledge necessary for the attack. The example also underscores the intersubjective as well as the intrasubjective character of discourse.

A clinical example of the intrasubjective aspect of this discourse is observed in obsession, where the superego (S1) functions as the agent commanding the subject (*$*) to control his bodily functions, including the anal one. Here, the subject obeying this order is also the other, who produces the necessary knowledge (S2) necessary for executing the order. In this particular case, the order is rather tall, because no matter how much knowledge we produce, we can never control the body completely (as is well attested by the various 'slips' of stool and tongue). But insofar as the obsessional person succeeds in controlling his bodily *jouissance* outside of the discourse – that is, outside of S1 – he or she succeeds in observing at least some of the set limits. Unfortunately, however, there is a surplus, object *a*, which is produced by the discourse: in this case the stools, which do not always obey the tall order of control.

To recapitulate: in the logic of the discourse, S1 constitutes the discourse for the subject (*$*) by opening it toward S2 and limiting it with respect to the Real outside of language. At the same time, it sets object *a* as surplus enjoyment, 'the-more-to-enjoy'. While in neurosis, the discourse is stable, in psychosis, there is no discourse with a stable character, even though psychotic subjects for shorter or longer periods of time may appear stabilized in a given discourse. However, as soon as the psychosis breaks out, the discourse will break down. Hence, while the neurosis is situated in a given discourse, the psychosis is outside the discourse and its dynamics, even though it is possible to locate a desire in some psychotic subjects.

Psycholinguistic Research Methods

S Garrod, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Psycholinguistics aims to uncover the mental representations and processes through which people produce and understand language, and it uses a wide range of techniques to do this. The preferred psycholinguistic method is to carry out a controlled experiment. This means that the researcher manipulates an independent linguistic variable to control some aspect of language processing and then measures the effect of the manipulation on a dependent variable of interest. For example, consider an experiment aimed at discovering the influence of the age of acquisition of a word (independent variable) on the time it takes an adult to identify that word (dependent variable). The psycholinguist would construct two lists of words, one containing words learned early in life, the other containing words learned later in life, and then measure the effect of age of acquisition (the independent variable) on the time to identify the word (the dependent variable). To make sure that the independent variable is the real cause of any effect observed in the dependent variable, the experimenter needs to carefully control that variable. For example, in the above experiment it is important to make sure that age of acquisition is not confounded with the length of the word or its citation frequency, because we know that longer words and low frequency words take longer to read.

Once the experiment has been run with a sufficient number of participants and a sufficient range of linguistic materials, the data is analyzed statistically. This usually involves taking the average of the values of the dependent variable (response latencies) for each value of the independent variable (each list of words acquired at different ages) and establishing whether the differences associated with the different values of the independent variable are statistically reliable. It is now standard in psycholinguistics experiments to test that the effects hold true both across the range of participants used in the experiment and across the range of linguistic materials used in the experiment.

Because the psycholinguist is interested in the dynamics of language processing, an important distinction is drawn between **on-line** techniques, which measure variables that tap into language processing as it happens, and **off-line** techniques, which measure variables related to the subsequent outcomes of processing. In practice, on-line and off-line techniques compliment each other, with off-line techniques used to determine the outcome of interpretation and on-line techniques used to determine its time course.

Another major distinction between psycholinguistic techniques relates to the nature of the dependent variables they measure. Some experiments have behavioral dependent variables, such as those associated with a reader's eye movements while reading, others have neurophysiological dependent variables such as those associated with electrical brain activity produced while listening to a sentence. The article first considers behavioral methods and then related neurophysiological methods. It starts with methods for the study of spoken and written language comprehension, and then methods for studying language production and dialogue.

© 2006 Elsevier Ltd. All rights reserved.

Psycholinguistics aims to uncover the mental representations and processes through which people produce and understand language, and it uses a wide range of techniques to do this. The preferred psycholinguistic method is to carry out a controlled experiment. This means that the researcher manipulates an independent linguistic variable to control some aspect of language processing and then measures the effect of the manipulation on a dependent variable of interest. For example, consider an experiment aimed at discovering the influence of the age of acquisition of a word (independent variable) on the time it takes an adult to identify that word (dependent variable). The psycholinguist would construct two lists of words, one containing words learned early in life, the other containing words learned later in life, and then measure the effect of age of acquisition (the independent variable) on the time to identify the word (the dependent variable). To make sure that the independent variable is the real cause of any effect observed in the dependent variable, the experimenter needs to carefully control that variable. For example, in the above experiment it is important to make sure that age of acquisition is not confounded with the length of the word or its citation frequency, because we know that longer words and low frequency words take longer to read.

Once the experiment has been run with a sufficient number of participants and a sufficient range of linguistic materials, the data is analyzed statistically. This usually involves taking the average of the values of the dependent variable (response latencies) for each value of the independent variable (each list of words acquired at different ages) and establishing whether the differences associated with the different values of the independent variable are statistically reliable. It is now standard in psycholinguistics experiments to test that the effects hold true both across the range of participants used in the experiment and across the range of linguistic materials used in the experiment.

Because the psycholinguist is interested in the dynamics of language processing, an important distinction is drawn between **on-line** techniques, which measure variables that tap into language processing as it happens, and **off-line** techniques, which measure variables related to the subsequent outcomes of processing. In practice, on-line and off-line techniques compliment each other, with off-line techniques used to determine the outcome of interpretation and on-line techniques used to determine its time course.

Another major distinction between psycholinguistic techniques relates to the nature of the dependent variables they measure. Some experiments have behavioral dependent variables, such as those associated with a reader's eye movements while reading, others have neurophysiological dependent variables such as those associated with electrical brain activity produced while listening to a sentence. The article first considers behavioral methods and then related neurophysiological methods. It starts with methods for the study of spoken and written language comprehension, and then methods for studying language production and dialogue.

Behavioral Methods

Common Assumptions Underlying Behavioral Methods

Although there is a wide range of behavioral psycholinguistic methods, most depend upon the same basic assumptions. One important assumption concerns how measurements of the time to carry out a task relate to inferences about complexity of processing. Whether the timed response be an eye movement or the time to answer 'yes' or 'no' to a question, it is assumed that the complexity of the mental process is reflected in the response latency. For example, if a reader takes longer to read the fragment "... raced past the barn fell" when it is part of the sentence "the horse raced past the barn fell" than the sentence "the horse that was raced past the barn fell," this is taken to reflect greater complexity in the syntactic analysis of the former than the latter. This assumption is used when interpreting results from most on-line techniques.

A more sophisticated timing methodology investigates the trade-off between speed to respond and accuracy of that response. This is called a **speed accuracy trade-off** (**SAT**) method. With SAT, participants are required to make some response to a linguistic stimulus as soon as they hear a tone, presented at different intervals after the presentation of the stimulus. When the interval is short, participants tend to make many errors, and when sufficiently long, they become completely accurate. So plotting response latency and accuracy across the range of tone intervals gives an unbiased measure of the rate at which the task can be carried out. SAT techniques have been used to assess the rate at which different kinds of lexical, syntactic, and semantic processing occur. Although it is considered a particularly refined technique for establishing processing rates, it has the disadvantage that many thousands of trials have to be run to produce a clear SAT profile, and this will mean that there will have to be many examples of each kind of material used. So there are only a limited number of issues that can easily be investigated with SAT.

Another important assumption underlying many behavioral methods concerns the interpretation of priming effects. **Priming** techniques measure the effect of having previously processed a **prime** item on the subsequent processing of a **target** item. The prime might be a word with a particular form or meaning or it might even be a whole sentence with a particular syntactic structure. The rationale behind priming techniques is that any influence of prime on the subsequent processing of the target must reflect some relationship between the mental representations of prime and target items. Typically, when a prime boosts the interpretation of the target (e.g., by speeding up the recognition of the target item), this is taken as evidence that there is something in common between the representation of target and prime. For example, if a person is quicker to decide that *giraffe* is a word having just read the word *tiger* than having just read the word *timer*, then it is assumed that this is due to the closer semantic relationship between *tiger-giraffe* than between *timer-giraffe*. On the hand, when it hinders the interpretation of the target – this is called **negative priming** as opposed to **positive priming** – this is taken to reflect some conflict between the representations of prime and target. Priming techniques are particularly useful for establishing the relationship between different linguistic representations used during processing and are widely used in conjunction with a number of behavioral or neurophysiological measures.

It is beyond the scope of this article to describe all the behavioral techniques that have been used in psycholinguistics. Instead, the article concentrates on techniques that have had a major impact on the field.

Behavioral Methods for Spoken Language Comprehension

Cross-modal Priming A common priming technique used to tap into spoken language comprehension is what is called **cross-modal priming**. In cross-modal priming the prime item is usually a word embedded in a spoken sentence or text used to prime a target item presented in written form, which is why it is called cross-modal. Consider the problem of working out how listeners resolve ambiguous words. Cross-modal priming can indicate the immediate interpretation of an ambiguous word, such as *bug*, in contexts that promote either one or other meaning of the word (e.g., 'insect' or 'listening device'). As participants listen to *bug* in the different contexts, they are presented with a written word (ANT or SPY) or a nonword (AST) and have to decide as quickly as possible whether the target is a word or not (this is called **lexical decision**). The question of interest is whether lexical decision of the targets ANT and SPY is boosted by hearing the prime *bug* in the different contexts. It turns out that when the visual target is presented immediately after hearing the prime in either context it promotes lexical decision for both targets. So this indicates that both interpretations ('insect' and 'listening device') are immediately activated irrespective of the disambiguating context. However, if the visual target is presented at a slightly later point (about 200 ms after the prime), only the target related to the contextually appropriate interpretation (i.e., ANT for 'insect' or SPY for 'listening device') is

primed. Cross-modal priming therefore indicates that all meanings of ambiguous words are accessed immediately on encounter, but then only the contextually appropriate meanings are retained as comprehension proceeds.

Cross-modal priming has been used to investigate many aspects of spoken language comprehension. These include influences of prior discourse context on lexical processing, resolution of anaphoric references (e.g., pronouns), and morphological analysis. The technique has the advantage that it can tap into spoken language comprehension as it occurs and often uncovers aspects of processing of which the subject is completely unaware, such as in the ambiguity experiment described above.

The Gating Technique Another technique for establishing when listeners interpret words in relation to information in the speech stream is **gating**. The gating procedure involves presenting increasingly long fragments of speech and measuring when listeners can interpret the speech appropriately. For example, if you want to know at what point a listener can accurately recognize the word *cathedral*, you can present them with the spoken fragments /ca/, /cath/, /cathe/ , /cathed/ . . . and record the listener's judgements for each fragment. The shortest fragment that can be correctly identified defines the point at which there is sufficient information in the speech for identification. This technique can be used to estimate the earliest point at which the listener could identify a word and so make it possible to test whether this predicts the recognition time for that spoken word.

The Visual World Paradigm One of the most effective on-line measures is **eyetracking** (recording the precise pattern of eye fixations during comprehension). Because visual attention is strongly controlled by where a person is currently looking, eyetracking can be used to indicate what a person is attending to at any point during comprehension and for how long they attend to it. The technique can either be used for reading research (see below), in which case the focus of attention corresponds to the words being looked at any time or it can be used to measure which part of a scene a participant attends to as they interpret spoken utterances about that scene. The latter technique is usually referred to as the **visual world paradigm**. A classic example of the use of this technique is in determining how listeners deal with syntactic ambiguities that arise during comprehension. For example, participants listen to instructions that are initially consistent with two syntactic analyses while they view a scene containing a small number of objects. They might be asked to *Put the frog on the napkin in the box* when there is either one or two frogs in the scene. Analyses of eye movements demonstrate that viewers look at the frog which is on a napkin more if there is also a frog that is not on a napkin than if there is no other frog present. From this it can be inferred that the visual context drives syntactic disambiguation (i.e., it supports the reading in which *on the napkin* syntactically modifies *frog* rather than being a syntactic argument of *put*) at an early stage in processing.

The visual world paradigm has been used to investigate a wide range of issues in spoken language comprehension. These include lexical access, resolution of anaphoric pronouns, development of strategies for semantic and syntactic processing, language development, and even language processing in dialogue. It offers a precise indication of when listeners integrate information from a linguistic utterance with that in the visual world and tends to show that comprehension is both incremental and immediate in relation to most levels of linguistic analysis.

Behavioral Methods for Written Language Comprehension

There are a variety of techniques that tap into the time course of written language comprehension.

Self-paced Reading One class of techniques is **self-paced reading**. The reader determines the rate at which written material is presented and the experimenter records the rate of presentation. A reader might be required to pace himself or herself sentence by sentence, phrase by phrase, or word by word. For example, in the word-by-word procedure, a word is presented, and as soon as the reader has understood it, he or she presses a key to trigger presentation of the next word. The sequence is then repeated until all the text has been read and the time to read each word is recorded. This kind of technique has been used to study syntactic analysis, discourse comprehension processes and in particular resolution of anaphors. It gives a good indication of when a reader encounters difficulty in comprehension, but is limited according to the size of linguistic unit being presented. Whereas larger units such as whole sentences can be read at a normal rate during self-paced reading, smaller units like words tend to be read much more slowly in self-paced reading tasks. Hence, when the technique has high on-line resolution (e.g., when word by word), it also interferes most with the normal reading process. This is not a problem with the eyetracking technique described below.

Rapid Serial Visual Presentation (RSVP) A slightly different technique for presenting written language

uses what is called **rapid serial visual presentation** (**RSVP**). With RSVP, readers see sequences of words in the center of a computer screen presented at a fixed fast rate. The experimenter then has the reader carry out an additional task, such as identifying a word in the sequence or trying to recall the sequence of words, which indicates how comprehension is limited by the rate of presentation. This technique has been used to investigate lexical, semantic, and syntactic processing. Like word-by-word self-paced reading, RSVP may well interfere with normal language processing.

Eyetracking During Reading The least interfering on-line behavioral technique for written language comprehension is eyetracking. During reading, the eye moves in a systematic way. There are brief **fixations** in which gaze stays on the same letter interspersed with fast movements called **saccades** during which the gaze moves to another letter or word of the text. For a skilled reader, 9 out of 10 saccades move the gaze from left to right to sample new material from the text, whereas 1 out of 10 saccades return the point of gaze to previously read material (these are called **regressions**). The duration of fixations and the length and direction of saccades (i.e., forward or backward movement of the gaze) directly reflect the ease or difficulty of the reading process. Furthermore, they indicate the precise word in the text that is causing reading difficulty because attention is only given to the word currently fixated.

The limited span of attention during reading can be demonstrated using the **moving window** technique in which a computer program controls dynamically the window of text presented to the reader as a function of where they are fixating. For example, with an asymmetric 12-letter window, the 4 letters to left and the 8 letters to the right of where the reader is fixating will be displayed as normal, whereas all the remaining text will be converted into random letters. The window of text together with its surround of random letters then changes as the point of fixation changes. One can reduce the size and form of the text window and measure when it begins to affect reading rate. It turns out that normal reading is quite possible when the window only contains the word currently fixated plus the first three letters of the next word on the line. However, there is a proviso that the material around the window must retain the spaces between the words in the original text. When the window arrangement is reversed so that the window contains random letters and the surround contains the normal text, readers encounter difficulty. With a reverse window of only 11 letters in width, reading becomes almost impossible.

Moving window studies indicate that readers only take in information from a limited region of text at any time during reading. This means that any extra time spent fixating the region must reflect processing difficulty associated with that region of text or previously fixated regions of text not completely processed but still held in memory.

Eyetracking has been used to study a wide range of linguistic processes, including lexical access, resolving lexical ambiguities, syntactic analysis, and various discourse processing phenomena, such as anaphora resolution. It is particularly effective in determining precisely when the reader makes a decision about some aspect of the linguistic input during sentence or discourse processing. For example, when presented with the sentence *We like the city that the author wrote unceasingly and with great dedication about* readers spend longer fixating the verb *wrote* as compared with the same verb in the fragment *We like the book that the author wrote unceasingly and with great dedication about*. This shows that readers immediately attempt to integrate each word of the sentence with the prior discourse and hence they detect the temporary anomaly produced by *wrote* in the first but not in the second sentence.

Eyetracking is a particularly effective technique because it does not interfere with the normal process of reading. A similar claim is made for some neurophysiological techniques such as ERP, described later.

Behavioral Methods for Spoken Language Production

Until the last decade, language production was not a central topic in psycholinguistics. This was partly because researchers did not have on-line methods for studying production in properly controlled experiments. This meant that the pioneering research on language production depended on off-line techniques, such as the study of speech errors. However, more recent work in language production has been influenced by on-line techniques. We consider both kinds of technique below.

Analysis of Speech Errors Speech error data has been used to draw many interesting conclusions about the nature of language production. For example, it was observed that substitution errors (e.g., saying *if **I** was done to that* rather than *If that was done to **me***) tend to always involve the same syntactic classes (e.g, the pronouns *me* and *that*). Also, as the example shows, the lexical substitution does not always involve a syntactic substitution. Otherwise, the error would have produced *If **me** was done to that*.

Such findings provide evidence that in production, words are chosen before they are strung together to make up an utterance and that this occurs before the words are marked for syntactic case.

Speech errors have been used to argue for an overall organization of speech production into separate message planning, lexical and grammatical assembly, and phonological processing components. There have also been some attempts to develop techniques to elicit speech errors experimentally by priming the errors in a similar fashion to that used in tongue twisters. Many of the conclusions drawn from the analysis of speech errors have been supported by results from more recent on-line techniques such as picture naming.

Picture Naming A particularly influential on-line technique for studying language production is to measure the time it takes participants to name pictures of objects or events. **Picture naming** is commonly combined with some form of priming task (see next section). It can also be combined with other techniques such as eyetracking to give a more precise indication of how words are accessed during language production. For example, a researcher might want to know whether speakers wait until they have all the words available before they start to articulate the first word in an utterance. To find out, the researcher could have participants name two pictured objects *A* and *B* in a phrase of the form *A and B*. If the time to start articulating the name of *A* is unaffected by the time to access the name for *B* as indicated by the time to articulate *B* in isolation, then the researcher can conclude that the speech articulation process begins before both word forms have been accessed. In fact, the evidence supports this conclusion.

Priming Techniques in Language Production An important issue in language production concerns the extent to which utterances are formulated incrementally one unit at a time according to different levels of representation (semantic, syntactic, and phonological). Priming techniques have been used to address this and other related questions. For example, at the phonological level words could be assembled for articulation either as complete packages or incrementally as sequences of distinct phonological units. A so-called **implicit priming** technique has been developed to test this. The participant has to learn sets of pairs of words, such that when given the first word in the pair he or she names the second word as quickly as possible. Crucially, in one condition the second words always share the same first syllable (e.g., single-loner, place-local, fruit-lotus), whereas in the other condition they do not (e.g., single-loner, signal-beacon, captain-major). The question is whether participants can use the implicit prime of the shared first syllable to speed up articulation. It turns out that they can, and more interestingly, the implicit priming only works for the first syllable in the word. When given a comparable list in which the second syllable of the second word is shared (e.g., single-murder, place-ponder, fruit-boulder), there is no articulatory benefit.

There are also techniques for studying priming at the syntactic level in production which use a variant of the picture naming procedure. A typical study might involve participants describing a sequence of pictured events using a verb indicated at the bottom of each picture. Interleaved between these descriptions, the participant checks descriptions they hear against another series of pictured events. By using ditransitive verbs such as *give*, which take either prepositional objects (*give the picture to Mary)* or double objects (*give Mary the picture*), it is possible to study syntactic priming independent of semantic priming. The question is whether having just heard *The sailor gave the banana to the nun* participants are more likely to describe their next picture as *The clown handed the book to the pirate* than *The clown handed the pirate the book*? It turns out that they are.

Behavioral Methods for the Study of Dialogue

As with language production, it is only quite recently that psycholinguists have begun the experimental investigation of language processing during dialogue. Again there is what has sometimes been called the problem of exuberant responses. Because dialogue is inherently spontaneous, how can the experimenter exert the control required for a sound experiment?

One way around this problem is to set up a task that controls what interlocutors can talk about. One such task is the **referential communication task**. One participant is required to describe a series of arbitrary visual patterns such that their partner who is able to reply can identify each pattern from the set that they have been given. This technique has been used to investigate how feedback from the listener affects the nature of subsequent references made by an interlocutor. More complex dialogue tasks have had conversational partners describe routes on a map or positions in a maze as part of some other cooperative activity. More recently, researchers have started to record interlocutors patterns of eye movements while carrying out some version of the referential communication task. In this way, it is possible to combine aspects of the visual world paradigm with those of the interactive referential communication task.

Neurophysiological Methods – ERP, fMRI, and MEG

Techniques for measuring the neurophysiological correlates of language processing have recently increased the psycholinguist's methodological armory. Three particular measurement techniques have been used. The first measures electrical activity at the scalp using **electro-encephalography** (**EEG**) to produce what are called **event-related brain potentials** (**ERPs**). The second measures changes in brain blood flow associated with neural activity using **functional magnetic resonance imaging** techniques (**fMRI**), and the third measures changes in magnetic fields associated with the electrical activity in the brain using **magneto-encephalography** (**MEG**). Each technique has its own advantages and disadvantages as a psycholinguistic tool.

fMRI signals give precise information about the area in the brain associated with the particular activity, so fMRI has proved useful for neurolinguistic investigation. The disadvantage with the technique for psycholinguistics is that it is not good for establishing the time course of the neural activity. This is because it takes time for the neural activity to produce changes in the blood flow. By contrast, ERPs provide precise information about the time course of the neural activity, but it is difficult to establish the source of the activity. This is because the ERP signal is affected by all sorts of irrelevant factors such as the thickness of the skull or interactions between signals from different areas of the brain. Finally, the most recently developed technique, MEG, offers good localization with similar temporal resolution to ERP. Nevertheless, like ERP signals, MEG signals are only sensitive to activity in neural structures with particular orientations, and neither technique is easy to apply when there is contemporaneous motor activity, such as eye movements or articulation during speech.

The most influential psycholinguistic research to date has tended to use ERP because it is both relatively cheap to run ERP experiments and the technique offers similar temporal resolution to that of behavioral measures such as eye tracking. This article concentrates mainly on the use of ERPs, but it will also say something about the use of MEG.

Event-related Brain Potentials (ERPs)

ERPs are derived from measurements of small changes in voltage at different points across the scalp. They are called **event-related potentials** because they are analyzed in relation to the onset of a triggering event. For instance, to derive an ERP that reflects word identification processes, the experimenter presents a word on a computer screen and measures the changes in scalp voltage from the point at which the word was presented. This process is then repeated over a number of trials. Because the data from each trial will contain irrelevant electrical activity, the experimenter takes the average potential across the set of related trials. In this way, the irrelevant 'noise' information can be filtered out. What remains is an ERP waveform with identifiable peaks and troughs of voltage. These peaks and troughs are taken to reflect the activity of bundles of nerve fibers in particular parts of the brain.

In practice, ERP researchers try to identify the characteristic peaks and troughs and establish how they might relate to concurrent processing. One well-established peak is called the **N400**, which corresponds to a negative component of the wave occurring approximately 400 ms. after presentation of the word that triggers it (it is a peak because ERP researchers conventionally plot negative values upward and positive values downward). The N400 has been associated with processes of conceptual or semantic integration of words into their sentential contexts. For example, when you measure ERPs elicited by the words *eat, drink,* or *cry* in the context "The pizza was too hot to *eat/drink/cry,*" then the N400 is larger for *cry* than *drink* and larger for *drink* than the contextually appropriate *eat*. This pattern is consistent with the idea that the N400 reflects conceptual integration (with *eat* being integrated into the sentence better than *drink*) as well as semantic integration (*drink* is semantically related to *eat* whereas *cry* is not).

Another characteristic trough is called the **P600** (a positive change occurring about 600 ms after the triggering word). Unlike the N400, the P600 has been associated with syntactic integration processes. For example, the word *was* when presented in the ungrammatical sentence *The doctor forced the patient was lying* produces a much larger P600 than *was* in the sentence *The doctor thought the patient was lying*. Because these two wave forms, N400 and P600, seem to reflect different kinds of processing, ERP can be used to establish the precise time course of these different processes. So ERP complements other on-line measures such as eyetracking, which do not differentiate between different kinds of psycholinguistic processes in this way.

ERPs have been used to address a wide range of questions both about early stages of lexical processing and more general syntactic and semantic processes in language comprehension. It is best suited for the study of processes that immediately follow presentation of the triggering stimulus because the ERP signal becomes increasingly noisy over time. This means that it is not such a good technique for studying such things as syntactic re-analysis or integration of a sentence into the discourse context.

Magneto-encephalography (MEG)

MEG has only recently begun to be used in psycholinguistics. MEG has some of the advantages of both fMRI techniques and EEG techniques because it enables precise source localization like fMRI and has fine temporal resolution like ERP. It also complements ERP. Whereas ERP electrical signals can only be picked up from nerve bundles that are in particular orientations with respect to the surface of the brain, MEG magnetic field signals can be picked up from nerve bundles that are orthogonal to those giving ERP signals. For these reasons, many researchers are particularly optimistic about MEG as a psycholinguistic method used together with ERP.

One particularly interesting application has been using MEG to establish the relationship between neural representation and linguistic form. The technique depends upon what has been called **mismatch negativity**. It was observed that as the same items are repeatedly presented to subjects, so the MEG signature associated with their processing is automatically reduced (probably because of neuronal habituation). However, when a new item is presented, the signal returns to normal. This happens irrespective of any behavior on the part of the subject. Mismatch negativity can therefore be used to establish the degree to which different items are processed in the same way. The greater the resumption of the activity (i.e., mismatch negativity), the more different the neurological processing of the new item. In this way, mismatch negativity can be used in a similar fashion to priming techniques to explore the neurological representation of different aspects of a linguistic stimulus.

Summary and Conclusion

Psycholinguistic techniques differ according to the kind of variables measured and the extent to which they tap into language processing as it happens. Behavioral measures, such as eyetracking, and neurophysiological measures, such as ERP, are particularly effective for measuring the time course of language comprehension. For language production studies, picture naming and priming techniques have been especially effective.

Our faculty for language has intrigued scholars for centuries. Yet most textbooks assume that psycholinguistics has its origins in the late 1950s and 1960s, and that nothing of note contributed to its evolution before then. In some respects this is true, in that it was only then that psycholinguistics began to proliferate as an identifiable discipline within the psychology literature. This proliferation was marked by the founding in 1962 of the *Journal of Verbal Learning and Verbal Behavior* (which subsequently, in 1985, became the *Journal of Memory and Language*). Why the original journal was so titled, and why its title presents us with a historical paradox, will become clearer as this review unfolds. The review's purpose is to consider how the present-day state of the art evolved. In so doing, it will touch briefly on ancient Greek philosophy, 19th century neuroscience, 20th century psycholinguistics, and beyond. It will

consider approaches to the brain as practiced in both ancient Egypt and modern neuroscience. It will be necessarily selective, in order to make some sense of the historical developments that contributed to psycholinguistic science.

From the Ancient Egyptians to the Greek Philosophers

The earliest to write about language and the brain were the ancient Egyptians – the first to write about anything at all. A catalog of the effects of head injury (and injuries lower down the body also) exists in what is now referred to as the Edwin Smith Surgical Papyrus, written about 1700 B.C. The writer (believed to have collected together information spanning perhaps another 1000 years before) referred there to what is presumed to be the first recorded case of aphasia – language breakdown following brain trauma. However, the Egyptians did not accord much significance to the brain, which unlike the other organs of the body, was discarded during mummification (it was scraped out through the nose). They believed instead that the heart was the seat of the soul and the repository for memory, a view largely shared by the Greek philosopher Aristotle (384–322 B.C.) – a somewhat surprising position to take given that he was a student at Plato's Academy and that Plato (427–347 B.C.) believed the brain to be the seat of intelligence.

Plato was possibly the earliest to write at length on language (where others may have spoken, but not written). Certainly, his writings were the most influential with respect to the philosophy of language and the question 'what does a word mean?' Plato, in his *Republic*, considered the meaning of words in his Allegory of the Cave (as well as in *Cratylus*). In this allegory, a group of prisoners have been chained all their lives within a cave. All they see are the shadows of objects cast upon a wall by the flames of a fire. They experience only those shadows (in much the same way that we can only experience the results of our sensory percepts), and their language similarly describes only those shadows. Plato noted that when using a word, the prisoners would take it to refer to the shadows before them, when in fact (according to Plato), they would refer not to objects in the shadow world, but (unbeknown to the prisoners) to objects in the real world. Thus, for Plato (and a host of more contemporary philosophers, from Frege to Puttnam), the true meaning of a word – its reference – is external to the person who, by using the word, is attributing meaning to it. But why should it matter what a word refers to?

The *psycholinguistic* endeavor is to uncover the mental processes that are implicated in the acquisition, production, and comprehension of language. Just as psychology is the study of the control of behavior, so psycholinguistics is the study of the control of linguistic behavior. A part of any psycholinguistic theory of mental process is an account of what constitutes the input to the mental process – that is, what information is operated upon by those processes. While Plato was of course correct that the form of the real-world object dictates the form of the sensory image presented to the allegorical prisoner, the mental processes involved in that prisoner's use of language can operate only on mental derivatives of that sensory image. There may be properties of the real-world object (such as color, texture, and density) that are not represented in their shadow-forms, and thus mental processes that might otherwise (outside the cave) develop sensitivity to those properties need never develop such sensitivities if constrained to living a life inside the cave. But while the shadows would not permit the distinction between, say, a tennis ball and an orange, the *contexts* in which the shadows were experienced, or their names heard, *would* distinguish between the two – mental sensitivities would develop, but they would not necessarily be grounded in the perceptual domain. These distinctions, between the actual world and our *experience* of the world, and between an object or word and the *context* in which that object or word might occur, led other philosophers, most notably Wittgenstein in his *Philosophical Investigations*, to propose that the meaning of a word is knowledge of its use in the language – that is, knowledge of the contexts in which it would be appropriate to utter that word, where such knowledge is shaped by experience. We return to this theme when we consider in more detail the more recent history (and possible future) of psycholinguistics.

The Earliest Empirical Studies

The pre-history of psycholinguistics (up until the 19th century) was dominated by philosophical conjecture. The term *dominated* is used loosely here, as there was no *systematic* and ongoing questioning of the relationship between mind and language, or indeed, brain and language – there was no *community* of researchers asking the questions. But modern-day psycholinguistics is dominated not by philosophy (although it had its moments), but by experimental investigations that measure reaction times, monitor eye movements, record babies' babbles, and so on. Its prehistory lacks such experimentation. This is not to say that no experiments were performed. Certainly, there were isolated cases, generally of a kind that would not

be tolerated in the modern age. Indeed, one of the most widely replicated studies (if one is to believe the historians) is a study that was carried out on at least three and possibly four independent occasions between the 7th Century B.C. and the 16th Century A.D. In each case, some number of babies were apparently brought up in isolation (except for carers who were either mute, or instructed not to speak), with the aim of the experiment being to discover what language, if any, the children would grow up speaking. The results varied. The Egyptian Pharaoh Psamtik (7th C.B.C.) was credited by Herodotus with discovering that they spoke Phrygian. The Roman emperor and German king Frederick II (1194–1250 A.D.) carried out a similar study, but all the infants died. King James IV (1473–1513 A.D.) is supposed to have performed a similar experiment on the island of InchKeith, although it is likely that this study never in fact took place (the fact that the children are reported to have emerged from their isolation speaking Hebrew is one reason to doubt the truth of the story). And finally, Akbar the Great (1542–1605), the grandfather of Shah Jahan who built the Taj Mahal, similarly failed to discover man's 'natural language' (although there is some suggestion that in this case, the infants acquired a form of signed language inherited, in part, from the infants' carers).

The 19th Century Emergence of the Cognitive Neuropsychology of Language

The first *systematic* studies of the relationship between language and brain were conducted in the 19th century. This is probably the earliest point in the history of psycholinguistics from when a *progression* of studies can be traced, with one author building a case on the basis of earlier studies coupled with newer data. The protagonists at this time were Gall, Boulliard, Aubertin, Broca, Wernicke, and Lichtheim, to name a few. None of them would be described as 'psycholinguists,' but to the extent that their work (like modern-day *cognitive neuroscientists*) informed accounts of the relationship between brain and language, they are no less a part of the history of psycholinguistics than are the linguists, philosophers, psychologists, and cognitive scientists who have influenced the field through their own, sometimes radically different, perspectives.

Franz Gall is perhaps better known for his work on phrenology, but he believed that language function was localized in the anterior parts of the brain. His student Jean Boulliard collected clinical evidence in support of Gall's theory, and in turn, Boulliard's student Ernest Aubertin did the same. It was at a meeting in April of 1861 that Aubertin made his beliefs plain: If a case of speech loss could be found that was not accompanied by a frontal lesion, he would give up his (and his intellectual forbearers') belief in the localization of language. In the audience was Paul Broca, after whom are named Broca's aphasia and, within the left frontal lobe, Broca's area. Broca was struck by Aubertin's empirical challenge, but at the same time realized that craniology (Gall's lasting influence on his students) could not provide the proof that was required to establish a link between language loss and cerebral localization – only anatomical inspection of the brain could do that. Coincidentally, within a few days he was presented with a patient suffering from speech loss who died a few days after that. Broca's postmortem analysis of this patient's brain (and the damage to what is now referred to as Broca's area), coupled with earlier observations made by Marc Dax (on right hemiplegia and its correlation with speech loss), but published at the same time, established the anatomical validity of the localization hypothesis. About 10 years later (in 1874), Carl Wernicke published his work on 'sensory aphasia' (deficits in the comprehension of language). This work was considerably enhanced by Wernicke's student Ludwig Lichtheim who, in 1885, produced a schematic (cf. a 'model') of how three interlinked centers in the brain are implicated in aphasia: Broca's (the 'center of auditory images'), Wernicke's (the 'center of motor images'), and a diffusely located 'concept center.' Lesions to each of these areas, or to the connections between them, produce different kinds of aphasias. Most interesting of all, his schematic enabled him to predict disorders that had not yet been described. This ability of a conceptual 'model' to make as yet untested predictions is a theme we shall return to.

The Early 20th Century Influence of Behaviorism

By the end of the 19th century, the study of language began to change, as did the study of psychology more generally. Interest in the psychology (as opposed to *philosophy*) of language shifted from being primarily (or even solely) concerned with its breakdown to being concerned also with its normal use. Wilhelm Wundt in *Die Sprache* (published in 1900) stressed the importance of mental states and the relationship between utterances and those internal states. William James similarly (at least early on) saw the advantages of introducing mental states into theories of language use (see his 1890 *Principles of Psychology*, in which several contemporary issues in psycholinguistics are foreshadowed). But the early 20th century was a turbulent time for psycholinguistics (as it was for psychology): J. B. Watson argued that psychology should be concerned with behavior

and behavioral observation, rather than with consciousness and introspection (the Wundtian approach). And whereas Wundt had argued that a psychology of language was as much about the mind as it was about language, behaviorists such as J. R. Kantor argued against the idea that language use implicated distinct mental states. For Kantor, the German mentalist tradition started by Wundt was simply wrong. Even William James turned away from Wundtian psychology. Thus, the behaviorist tradition took hold.

The late 19th and early 20th centuries were a time of great change in linguistics, too. The 19th century had seen the emergence of the Neogrammarians, a group that studied language *change*. They were interested in how the sounds of different languages were related, and how within a language, the sounds changed over time. They were less interested in what a language 'looked like' at a particular moment in time. This changed at the beginning of the 20th century when Ferdinand de Saussure brought *structure* into the study of language. He introduced the idea that every element of language could be understood through its relation to the other elements (he introduced *syntactic* distinctions that are still central to contemporary linguistics). In the 1930s, the Bloomfieldian school of linguistics was born, with the publication in 1933 of Leonard Bloomfield's *Language*. Bloomfield reduced the study of language structures to a laborious set of taxonomic procedures, starting with the smallest element of language – the *phoneme*. In doing so, Bloomfield firmly aligned the linguistics of the day with behaviorism. And just as behaviorism eschewed mental states in its study of psychology, so the Bloomfieldian tradition eschewed psychology in its study of language. The study of language was firmly caught between the proverbial rock and a hard place – between behaviorism on the one hand and taxonomy on the other. Mental states were, the argument went, irrelevant – whether with respect to psychological or linguistic inquiry.

The behaviorist tradition culminated (with respect to language) with B. F. Skinner's publication in 1957 of *Verbal Behavior*. Here, Skinner sought to apply behaviorist principles to verbal learning and verbal behavior, attempting to explain them in terms of conditioning theory. Verbal behavior (and *Verbal Behavior*) proved to be the final battleground on which the classical behavorists and the mentalists would clash.

The Mid-20th Century and the Chomskyan Influence

In 1959, Chomsky published a review of Skinner's *Verbal Behavior*. He argued that no amount of conditioned stimulus-response associations could explain the infinite productivity or systematicity of language. With Chomsky, out went Bloomfield, and in came mental structures, ripe for theoretical and empirical investigation. Chomsky reintroduced the mind, and specifically mental representation, into theories of language (although his beliefs did not amount to a theory of psychological process, but to an account of linguistic structure). So whereas Skinner ostensibly eschewed mental representations, Chomsky apparently proved that language was founded on precisely such representation. Some later commentators took the view that the Chomskyan revolution threw out the associationist baby with the behaviorist bathwater. Behaviorism was founded on associationism. Behaviorism was 'out,' and with it, associationism. Symbolic computation was 'in,' but with it, uncertainty over how the symbolic system was acquired. It was not until the mid-1980s that a new kind of revolution took place, in which the associationist baby, now grown up, was brought back into the fold. The intervening 20 years were typical teenage years – full of energy, punctuated by occasional false hopes that nonetheless proved essential to the maturation process.

Two years before his review of *Verbal Behavior*, Chomsky had published *Syntactic Structures*, a monograph devoted to exploring the notion of abstract grammatical rules as the basis for generating sentential structure. According to Blumenthal in his 1970 account of the history of psycholinguistics, Chomsky's departure from the Bloomfieldian school was too radical for an American publisher to want to publish a lengthy volume that Chomsky had written outlining the new approach, and only Mouton, a European publisher (and presumably more sympathetic to the tradition that Chomsky was advocating) would publish a shorter monograph based on an undergraduate lecture series he taught at MIT. In fact, this is not quite accurate (N. Chomsky, personal communication); Chomsky had indeed written a longer volume (subsequently published in 1975), and it is true that initial reactions to the manuscript were negative (but, according to Chomsky, not unreasonable), but *Syntactic Structures* was not a compromise brought about through Chomsky's search for a publisher; he had not, in fact, intended to publish it. Instead, Cornelis van Schooneveld, a Dutch linguist and acquaintance of Chomsky's who was visiting MIT and happened to edit a series for Mouton, suggested that Chomsky write up his class notes and publish them. This he did, and modern linguistics was born. Psycholinguistics became caught up, almost immediately, in its wake.

Chomsky's influence on psycholinguistics cannot be overstated. He drew an important distinction

between 'competence,' or the knowledge we have about a language, and 'performance,' the use of that language (a distinction that was reminiscent of Saussure's earlier distinction between *langue* and *parole*). Both, he claimed, arise through the workings of the human mind – a mind, which furthermore is innately enabled to learn the structures of human language (although not everyone agreed with the arguments for a language acquisition device akin to a mental organ – a concise summary of the counterarguments was written by Bates and Goodman (1999)). It is perhaps surprising that against the backdrop of *Syntactic Structures* and Chomsky's *Review of Skinner's Verbal Behavior*, a new and influential journal dedicated to research into the psychology of language should nonetheless, in 1962, give itself a title (the *Journal of Verbal Learning and Verbal Behavior*) that firmly placed it in the behaviorist tradition.

From Linguistic Competence to Psychological Performance

Chomsky's theories of grammar were theories of competence, not performance. And yet, his work on *transformational grammar* initiated a considerable research effort in the early 1960s to validate the psychological status of syntactic processing (the construction of representations encoding the dependencies between the constituents of a sentence). Many of these studies attempted to show that perceptual complexity, as measured using a variety of different tasks, was related to linguistic complexity (the so-called Derivational Theory of Complexity). However, whereas the syntactic structures postulated by transformational grammar did have some psychological reality, the devices postulated for building those structures (e.g., the transformations that formed a part of the grammatical formalism) did not. It soon became apparent that the distinction between competence and performance was far more important than originally realized – the linguists' rules, which formed a theory of competence, did not make a theory of psychological process.

Subsequently, the emphasis shifted toward examination of the psychological, not linguistic, mechanisms by which syntactic dependencies are determined (a process referred to as *parsing*). In a seminal paper published in 1970, Thomas Bever pointed out that in cases of ambiguity, when more than one structure (i.e., dependency relation) might be permissible, there appear to be consistent preferences for one interpretation rather than another. This consistency appeared to hold not only across different examples of the same kind of ambiguity, but across different people, too. Thus, despite the grammaticality of '*the horse raced past the barn fell*' (cf. '*the car driven past the garage crashed*'), the preference to interpret '*raced*' as a main verb (instead of as a past participle equivalent to '*driven*') is so overwhelming that the sentence is perceived as ungrammatical (and the preference is then said to induce a 'garden path' effect). Evidently, grammaticality and processability are distinct mental phenomena.

On the Influence of the Digital Computer

The 1970s saw enormous growth in psycholinguistics. Advances were made across a wide range of phenomena, including the identification of both printed and spoken words, the reading process, sentence comprehension (with much of the emphasis on the resolution of ambiguities of the 'garden path' kind), and the mental representation of texts. Whether there was a 'spurt' in the number of publications is contentious, because although there undeniably was such a spurt, the whole of psychology experienced the same rapid growth. It would be wrong, however, to attribute all this advancement to the influence of Chomsky. The demise of behaviorism played a part (and certainly Chomsky played a part in that demise), but so did the advent in the 1950s of the digital computer. The 'mind-as-computer' metaphor had a subtle but pervasive influence on both psycholinguistics and the study of *cognition* generally. Computer programs worked by breaking down complex behaviors into sequences of simpler, more manageable (and hence more understandable) behaviors. They relied on *symbol manipulation* and the control of *information flow*. They distinguished between different levels of explanatory abstraction (the high-level programming language, the assembly code, and the flow of electrical currents around the hardware). And perhaps most important of all to the empirical psychologist, they enabled novel predictions to be made that might not otherwise have been foreseen had the 'model' not been implemented in full; complex interactions among the components of a program were not easy to foresee.

The influences of the digital computing revolution were felt in different ways. Some were direct, with researchers building computer simulations of mental behavior (in the growing field of *Artificial Intelligence*, several language 'understanding' programs were written, some of which are still relevant 35 years later – e.g., Terry Winograd's SHRDLU program written in 1968–1970). Other influences were indirect, coming to psycholinguistics via philosophy. One such example was Jerry Fodor's Modularity of Mind hypothesis (from 1983). One simplified interpretation of

this hypothesis (it was interpreted in different ways by different researchers) was that there are two alternative ways of theorizing about the mind: one is to assume it is incredibly complex and that multiple sources of information interact in multiple ways, and the other is to assume that it can be broken down into a number of modules, each of which performs some particular function and is 'blind' to the workings of the other modules (perhaps taking as input the output of one or more of those other modules). Fodor argued that certain aspects of cognition were modular (the input systems), and certain others were not (central processes). This hypothesis had considerable influence in psycholinguistics, and for a time (the mid-1980s to early 1990s), hypotheses were evaluated according to whether they were modular or not. There seemed little agreement, however, on where one drew the boundaries (for example, was spoken language recognition a part of an input system? If it was, how could 'higher-level' knowledge of the context in which the language was being interpreted influence the modular and encapsulated recognition process? – Some argued it could not, while others argued it could). It was about this time, in seeming opposition to the trend toward *symbolic computation*, that a new computationally motivated approach to cognition emerged in the mid 1980s, apparently eschewing symbolic computation *and* modularity.

The Late 20th Century Emergence of Connectionism: Statistical Approaches to Language

In 1986, David Rumelhart and Jay McClelland published *Parallel Distributed Processing*. This edited volume described a range of *connectionist*, or *neural network*, models of learning and cognition, and marked a 'coming of age' for connectionism. It was, for many researchers in psycholinguistics, their first introduction to a wide range of research in this emerging field. Of particular interest were the facts that 'knowledge' in connectionist networks is encoded as patterns of connectivity distributed across the neural-like units, and 'processing' is manifest as spreading patterns of activation. These networks can learn complex associative relations largely on the basis of simple associative learning principles (based primarily on work published in 1949 by Donald Hebb, a student of Lashley's). Various algorithms exist to set the 'strengths' of the connections between the units automatically, so that a given input pattern of activation across some set of units will spread through the network and yield a desired output pattern across some other set of units. Indeed, multiple input-output pairings can be learned by the same network. Importantly, and in contrast to the ideals of the behaviorist traditions, neural networks can develop internal representations.

Several connectionist models had profound effects on developments in psycholinguistics. TRACE, for example, developed by McClelland and Jeff Elman in the 1980s, was a model of spoken word recognition that formed the focus of empirical research for a good 20 years after its inception. But TRACE did not learn anything – it was hardwired. An extremely influential model that *did* learn by itself was described by Elman (1990), who showed how a particular kind of network could learn the dependencies that constrain the sequential ordering of elements (e.g., phonemes or words) through time. In effect, it learned which kinds of word could follow which other kinds of word (hence, it was a *statistical model*, because it encoded the statistics of the language it was trained upon). Interestingly, it developed internal representations that appeared to resemble grammatical knowledge; words that occurred in similar sentential contexts came to evoke similar internal representations (that is, internal patterns of activity when the word was presented to the network) – and because words of the same grammatical category tend to occur in the same sentential contexts, different 'clusters' of words emerged, with each cluster representing a different category of word.

Not surprisingly, the entire connectionist enterprise came under intense critical scrutiny from the linguistics and philosophy communities, not least because it appeared to reduce language to a system of statistical patterns, was fundamentally associationist, nonmodular, and eschewed the explicit manipulation of symbolic structures (because the internal representations that emerged as a result of the learning process were not symbolic in the traditional sense). Within the context of the symbolic-connectionist debate there developed what became perhaps one of the longest surviving disputes in contemporary psycholinguistics; between those that believe that word formation (e.g., the formation of 'walked' from 'walk,' 'ran' from 'run,' and 'went' from 'go') is driven by knowledge of *rules* and *exceptions* to those rules, and those who believe it is driven by *statistical regularity* (which can apparently capture, in the right model, both the regularly and irregularly formed words). The debate shows little sign of abating, even 20 years later.

Critics notwithstanding, statistical approaches to language (both with respect to its structure and its mental processing) are becoming more prevalent, with application to issues as diverse as the 'discovery' of words through the segmentation of the speech input, the emergence of grammatical categories, and even the emergence of meaning as a consequence of

statistical dependencies between a word and its context (cf. Wittgenstein's views on the meaning of words). Empirically also, the statistical approach has led to investigation of issues ranging from infants' abilities to segment speech and to induce grammar-like rules to adult sentence processing. The reason that such approaches have proved so appealing is that statistics are agnostic as to the nature of the real-world objects over which the statistics are calculated – thus, the fundamentally same algorithm can be applied to sequences of phonemes, words, or sentences. Their implementation within a neural network is similarly agnostic – the same network and the same algorithms that enable that network to induce the appropriate statistics can be applied to many different domains. Connectionism opened up experience-based learning to a range of psychological domains, not just the linguistic domains. And experience-based learning was attractive not least because it required fewer assumptions about the existence of innately specified domain-specific faculties (and in a multi-authored volume published in 1996, Jeff Elman teamed up with a variety of developmental psychologists to argue that connectionism was attractive precisely because it enabled a new perspective on how innate constraints on learning and neural structure might be an important component of human language acquisition (Elman, 1996)).

Neural networks can be criticized for being (among other things) too unconstrained – they can, in principle, do more than might be humanly possible – but the opposite criticism, that they are too small and do not necessarily 'scale up' is another criticism that is often heard. Neural networks as currently implemented are just the 'medium' on which are offered up the statistics. To misuse a common adage, the proof will be in the pudding, not in the plate that serves it up. There is little doubt, from the historical perspective, that although the emergence of connectionism has offered a powerful theoretical tool, its emergence has also polarized sections of the psycholinguistic community, between 'connectionists' on the one hand, and 'symbolists' on the other. This polarization is not unique to psycholinguistics, however, but pervades the study of cognition more broadly. And as if to further muddy the theoretical waters, the beginning of the 21st century has seen renewed interest in yet another (no less controversial) paradigm – one that grounds language (and cognition) in action.

The Early 21st Century and the Grounding of Language in Action and the Brain

Traditional theories in cognition suppose that the job of the perceptual system is to deliver to the cognitive system a representation of the external world. The job of the cognitive system is then to reconstruct, mentally, that external world. This reconstruction subsequently forms the basis for 'commands' sent to, for example, the motor system. Cognition thus mediates between perception and action. An alternative approach, termed 'embodied cognition,' is that cognition and action are encoded within the same representational medium. Cognition is thus rooted in the same motoric and sensory representations that support interaction with the external world. Or, put another way, cognition is grounded in the same neural substrates that support sensory-motoric interaction with the external world. One consequence of this view is that language, a component of cognition, should, like the other components of cognition, be studied in the context of (i) the interactions it causes between the hearer and the world, and (ii) the neural substrates that support those interactions. Coincidentally, the 1990s saw a boom in research into the neural substrate of language, in part due to the increased availability of neuroimaging technologies (predominantly *PET* and *fMRI,* with *EEG* and more recently *MEG* also proving influential). It also saw increased research into the relationship between language and action. Taken together, these two streams of research provided increasing evidence for embodied cognition.

With respect to imaging, a variety of studies demonstrated what Lichtheim had alluded to a century earlier – that concepts are not represented in some discrete location within the brain, but are distributed across different regions. For example, words whose meanings implicate tool use (e.g., 'hammer') activate regions of the brain responsible for controlling motoric action (during the use of the tool) and other regions involved in the recognition of object form (during perception of the tool). Color words (e.g., 'yellow') and words referring to non-manipulable artefacts (e.g., 'house') do not activate motoric areas to the same extent, but they do activate regions close to those implicated in form perception and, for color words, color perception. Importantly, there is no single region that is primarily active; rather, words and concepts activate complex patterns of activity that are distributed and overlapping within different parts of the brain that are known to have (other) motoric and sensory functions. The meanings of (at least some) words do appear, then, to be grounded in those neural substrates that support sensory-motoric interaction.

About the same time that increased attention was focusing on neuroimaging, new techniques for studying language and its effects on *action* were also being developed. One of these involved the monitoring of eye movements as participants listened to

commands to manipulate objects in front of them, or as they listened to descriptions of events that might unfold within the scene before them (one can view language-mediated eye movements as central to the relationship between language and action, because eye movements signal overt shifts in attention, and because attention to something necessarily precedes (deliberate) action upon it). It was found that eye movements were closely synchronized with processes implicated in both spoken word recognition and sentence processing, and that much could be gleaned about what kinds of information were recruited at what point during a word or sentence in order to interpret the unfolding language with respect to the scene in front of the participant (it is not without some irony that in L. N. Fowler's famous Phrenology bust, from about 1865, the faculty for language is located just below the left eye). Another technique involved measuring motoric responses to different kinds of linguistic stimuli – for example, words or sentences referring to movements toward or away from the body were found to interfere with responses in a judgment task (e.g., 'does this sentence make sense?') that involved moving a finger toward or away from a response button. A range of studies, some involving TMS (Transcranial Magnetic Stimulation – a method for either temporarily stimulating or suppressing a part of the brain, such as parts of motor cortex) have confirmed this motoric component to language comprehension.

It is noteworthy, with respect to the embodiment approach to cognition, that some of its basic tenets have been around since the earliest days of (contemporary) psycholinguistics. Winograd's SHRDLU program, for example, viewed the meaning of a word such as 'place' or 'lift' as that part of the program that caused placing or lifting – language comprehension within that program was grounded in sensory-motoric representation – and as such, SHRDLU followed in the Wittgenstinian tradition of treating meaning as use. Similarly, it is noteworthy that although most of the neuroimaging of language has been carried out independently of theories of embodied cognition, much of the work converges on the same theme – that aspects of language are represented in the same representational substrates that control our sensory-motoric interactions with the external world.

Epilogue

And that, broadly speaking, is where the field is now. In the space available, it is impossible to document all the trends that have influenced contemporary psycholinguistics, and which have influenced not just what kinds of language behavior we study (e.g., language breakdown, normal language use, ambiguity resolution, and so on), but also how we study those behaviors (through studying aphasis, neuroimaging, language-mediated eye movements, and so on). And we have still to see the full influences of connectionism, statistical learning, embodied cognition, and the neuroscience of language. What we can be sure of is that the boundaries between the study of language and the study of other aspects of cognition are wearing thinner (the eye movement research mentioned above is at the interface of language and vision, for example). No doubt there are already developments in 'neighboring' fields of study (e.g., the computational sciences and non-cognitive neurosciences) that will also have an impact, but have yet to emerge as quantifiable influences on psycholinguistics. For example, researchers are already using computational techniques coupled with detailed neuroanatomical research on the neural structure of the brain to attempt to understand the kinds of 'computation' that distinct parts of the brain may be capable of. Such research promises greater understanding of the brain's ability to learn, represent, and deploy language. And although the history of psycholinguistics is relevant to understanding where the field is today, perhaps of greater interest is where the field will be tomorrow.

Acknowledgments

This article is a substantially expanded version of a short, 1500-word section on the history of psycholinguistics that appeared as part of a broader review of issues in psycholinguistics (Altmann, 2001). The reader is referred to this paper for in-depth review of (some of) the topics that constitute the field of psycholinguistics. The author would like to thank the publishers of this article for donating his fee to the charity Médecins sans Frontières, and Silvia Gennari for advice on topics ranging from Plato to neuroimaging.

Emergence of Psycholinguistics in the Late 1950s and 1960s from the Chomskyan Revolution

Although the study of language has been part of psychology from its earliest years, including for example in the work of Wilhelm Wundt, the father of psychology, a distinct field of psycholinguistics emerged in the late 1950s largely in response to the impact of Chomsky. In the preceding decades, notably in the United States, psychology had been dominated by the behaviorist approach of researchers such as B. F. Skinner. They treated language as a form of verbal behavior, which, like all other behavior, they believed was governed by simple stimulus–response associations. Chomsky demonstrated the shortcomings of the behaviorist approach in explaining the productivity of language and its complexity, and his work, notably *Syntactic structures* (1957), provided a major impetus for a new kind of psychological investigation of language. This was driven by an interest in the mental representation of language in general and syntactic structures in particular (*see* **Psycholinguistics: History**).

Psychology since the demise of behaviorism has again been concerned with understanding the way that people accomplish various information-processing tasks. In the field of psycholinguistics this means a concern with the cognitive processes by which a string of sounds in an utterance, or marks on a page, are processed to identify individual words and sentences, and how this emerging structure becomes mentally represented as a meaningful concept. The goal of this process is to derive models that account for how people achieve this so rapidly and successfully, given what we know about the general limitations of human cognitive processing. To oversimplify: the psychologist is concerned with **how** the linguistic units are processed and represented; the linguist is concerned with the description of the structures that emerge from any such processes.

Research Topics in the Early Years of Psycholinguistics

In its early years psycholinguistics reflected the concerns of linguistics and the central role of syntax. Psychologists such as Miller and Isard (1963) showed that the syntax influences the way people interpret sentences, and even how many words people can remember from a string of words that make no sense. More words are remembered from a 'sentence' like 'Accidents carry honey between the house' than from strings with no syntactic structure such as 'On trains hive elephants the simplify.' The focus on

Emergence of Psycholinguistics in the Late 1950s and 1960s from the Chomskyan Revolution

Although the study of language has been part of psychology from its earliest years, including for example in the work of Wilhelm Wundt, the father of psychology, a distinct field of psycholinguistics emerged in the late 1950s largely in response to the impact of Chomsky. In the preceding decades, notably in the United States, psychology had been dominated by the behaviorist approach of researchers such as B. F. Skinner. They treated language as a form of verbal behavior, which, like all other behavior, they believed was governed by simple stimulus–response associations. Chomsky demonstrated the shortcomings of the behaviorist approach in explaining the productivity of language and its complexity, and his work, notably *Syntactic structures* (1957), provided a major impetus for a new kind of psychological investigation of language. This was driven by an interest in the mental representation of language in general and syntactic structures in particular (*see* **Psycholinguistics: History**).

Psychology since the demise of behaviorism has again been concerned with understanding the way that people accomplish various information-processing tasks. In the field of psycholinguistics this means a concern with the cognitive processes by which a string of sounds in an utterance, or marks on a page, are processed to identify individual words and sentences, and how this emerging structure becomes mentally represented as a meaningful concept. The goal of this process is to derive models that account for how people achieve this so rapidly and successfully, given what we know about the general limitations of human cognitive processing. To oversimplify: the psychologist is concerned with **how** the linguistic units are processed and represented; the linguist is concerned with the description of the structures that emerge from any such processes.

Research Topics in the Early Years of Psycholinguistics

In its early years psycholinguistics reflected the concerns of linguistics and the central role of syntax. Psychologists such as Miller and Isard (1963) showed that the syntax influences the way people interpret sentences, and even how many words people can remember from a string of words that make no sense. More words are remembered from a 'sentence' like 'Accidents carry honey between the house' than from strings with no syntactic structure such as 'On trains hive elephants the simplify.' The focus on

syntax and its importance in language processing led many psycholinguists to try to test the psychological reality of Chomsky's theory of generative grammar. Experiments were designed to explore the notion that when people process sentences, what they are doing is retrieving the deep syntactic structure as described in Chomsky's transformational grammar. So initially, a number of studies seemed to show that the relative ease or difficulty with which a reader or listener could process a given sentence was directly related to its syntactic complexity. Chomsky's kernel sentences, equivalent to active affirmative declarative sentences, were recalled most easily and processed most quickly, while sentences including one or more transformations such as negative or passive forms were more difficult to process. These kinds of study led to the so-called derivational theory of complexity. This was superseded as it became clear that the results of many of the studies that apparently provided support for this purely syntactic view of how people process sentences could also be accounted for by the influence of semantic factors. Although sentence processing remains one of the most significant topics in psycholinguistics, the range of language phenomena that are studied has broadened considerably since the early 1960s. The assumption that the role of psycholinguistics is to demonstrate the psychological validity of any particular syntactic theory has also been overtaken.

Models of Sentence Comprehension

Many of the models of sentence comprehension that have been developed in psycholinguistics try to elucidate the cognitive processes that are involved when a reader or listener interprets a sentence. There is considerable experimental evidence that sentence comprehension is incremental, that is, that an interpretation is built up on a moment-by-moment basis from the incoming linguistic information. The evidence for this incremental processing is particularly striking in the way listeners recognize spoken words (see below), which are often identified before all the acoustic information has been heard.

Even in written language processing we have clear signs of the incremental nature of linguistic processing. This is illustrated by the difficulties most readers have with sentences like the following: 'The horse raced past the barn fell' (Bever, 1970). This is known as a garden path sentence, because nearly all readers interpret this **while** they are reading, with 'raced' as an active verb and so expect the sentence to end after 'barn.' They do not realize that the sentence could have an equivalent interpretation to 'The horse that raced past the barn, fell.' The incremental way that sentences seem to be interpreted by readers or listeners is a major source of potential ambiguities of interpretation. Many sentences in a language have potentially more than one interpretation as they are processed, yet the reader or listener is usually not aware of any problem in arriving at one clear interpretation of a sentence.

The cognitive architecture that underpins such an achievement has been a source of much debate in psycholinguistics. Some researchers have held that in the frequent cases where more than one analysis of a sentence is possible, the reader or listener computes all possible analyses in parallel. The difficulty of garden path sentences has led others to propose serial models, where it is assumed that a single analysis is computed and corrected later if this is needed. Models have been proposed to account for the empirical evidence on sentence-processing difficulties. These often involve various versions of parallel analyses, where candidate analyses are only active for a brief period of time or are ranked according to frequency in the language or plausibility with the context. One of the most influential of these accounts is the constraint-based model of MacDonald *et al.* (1994). The weightings attached to each candidate analysis are based on the frequency of a syntactic structure in the language, the plausibility of the words in the sentence to their assigned syntactic roles, etc. So this model is an example of an interactive model where many different sorts of information, syntactic, semantic, pragmatic, contextual, and frequency, can all play simultaneous roles by activating alternative interpretations of the incoming linguistic information. In models of this type, semantic factors can override syntactic processing biases. This model is attractive to psychologists for a number of reasons. It is amenable to modeling by connectionist approaches (*see* **Cognitive Science: Overview**) and it avoids the problem of having to base cognitive processes on syntactic rules, which for psychologists appear to change arbitrarily with changes in linguistic theories.

In contrast, one of the other most influential models of sentence processing is the garden path model (Frazier, 1979). This uses only syntactic principles in its initial stage. An analysis is computed based on two syntactic preferences, the most important being the principle of minimal attachment, the other being the principle of late closure. The first principle means that the parsing of the sentence that produces the simplest parse tree, with fewest nodes, takes precedence. So a sentence like 'Mary watched the man with the binoculars' is usually interpreted to mean that Mary (not the man) was using binoculars. According to Frazier's interpretation of phrase structure rules, this interpretation involves one node fewer than the alternative and so demonstrates the principle of minimal

attachment in action. This principle takes precedence over the principle of late closure. This is the preference to attach incoming materials to the current phrase or clause. This latter principle is used to explain the preference for interpreting sentences like 'John said he will leave this morning' to mean that the phrase 'this morning' relates to the verb 'leave,' not the verb 'said.'

As part of the ongoing debate about the adequacy of different models of the parsing process there has been an active discussion in the experimental literature over several years about the extent to which semantic factors can override or guide the analysis of syntactic structure. This has been explored in several studies focusing on the ease or difficulty with which sentences containing reduced relative clauses can be processed. Several studies have tested how people interpret sets of sentences like the following:

(1a) The defendant examined by the lawyer turned out to be unreliable.
(1b) The defendant that was examined by the lawyer turned out to be unreliable.

(2a) The evidence examined by the lawyer turned out to be unreliable.
(2b) The evidence that was examined by the lawyer turned out to be unreliable.

Sentences like (1a), which contain a reduced relative clause, are more difficult to process than their equivalent full relative clause (1b). Readers initially treat 'examined' as a main verb whose subject is 'the defendant.' They then have to reanalyze this garden path when they reach the phrase 'by the lawyer.' The argument is the extent to which structurally similar sentences (e.g., [2a]) cause readers to have equivalent processing problems. This is what might be expected from a purely syntactic view of parsing. In contrast, in an interactive constraint-based model, the semantic implausibility of interpreting an inanimate noun such as 'evidence' as the subject of the verb 'examined' should protect the reader from the need to reanalyze an initial incorrect syntactic structure.

Trueswell *et al.* (1994) seemed to show just such a pattern. This was considered powerful evidence in support of interactive constraint-based models of sentence processing. More recently, Clifton *et al.* (2003) have challenged the evidence that semantic factors override syntactic processing in the initial stages of parsing. They used more sophisticated techniques for monitoring and analyzing eye movements to determine the processing difficulties experienced by readers. They found that reduced relative clauses caused disruption to processing, irrespective of the semantic plausibility of the relationship between the apparent subject and main verb. Semantic factors, however, influenced how quickly the readers **recovered** from their wrong analysis of the syntax of the sentence. Clifton *et al.* (2003) stressed that the key thing for psycholinguistic models of sentence processing is not whether the data on processing reduced relative clauses support garden path or constraint-based models. They claim that the important goal is to develop parsing models that deal both with the task of creating structure and evaluating the structure that is created.

Although there have been numerous studies of sentence processing conducted by psycholinguists over the decades, the vast majority of these have focused on how readers interpret written sentences. A few studies have tackled the issue of how listeners use the cues in spoken language during parsing. Minimal attachment strategy can be shown to be overcome by the prosodic cues in real spoken sentences. Similarly, the principle of late closure, which can cause syntactic ambiguities in written sentences, can be less problematical in spoken materials because of clear prosodic cues to the intended interpretation. Even the apparent errors in spoken sentences, such as the disfluency 'uh,' can have an impact during the parsing process. Bailey and Ferreira (2003) presented sets of sentences to listeners such as the following:

(3a) Sandra bumped into the busboy and the uh uh waiter told her to be careful.
(3b) Sandra bumped into the busboy and the waiter uh uh told her to be careful.

These sentences are ambiguous up to the point when the listeners hear 'told.' 'Sandra' could have bumped into 'the busboy' or 'the busboy and the waiter.' Yet the listeners who heard the materials most often interpreted sentences like (3a) to mean that 'the waiter' was the subject of a new clause, i.e., that it was the subject of the verb 'told.' This shows that disfluencies can systematically influence the way listeners parse incoming sentences. The same effect was observed when the interruption was not a disfluency but an environmental sound such as a telephone ringing.

Speech Production and Speech Errors

These studies represent a welcome aspect of the broadening of the psycholinguistic research agenda to include more consideration to the production and comprehension of spoken as well as written language. The study of speech disfluencies is one part of this. Speech disfluencies encompass a range of phenomena, including pauses in speech such as silences, filled pauses, and fillers such as 'uh' and 'um,' as well as speech errors such as slips of the tongue, spoonerisms, and malapropisms. When we speak we aim to

produce a grammatically well-formed utterance with no noticeable hesitations. Yet this ideal delivery cannot always be achieved. It is estimated that around 5% of words in speech are disfluent in some way. Yet these disfluencies are not random in their patterns of occurrence. Even the similar-sounding disfluencies 'uh' and 'um' have been shown to have systematic contexts of use. Speakers use 'uh' before a short delay in their speech production but use 'um' before a more significant delay. Speakers seem to become disfluent because they are experiencing some kind of problem in planning and producing their utterance. Speakers have been found to pause more before unpredictable words, suggesting they might be experiencing word-finding difficulties. Speakers also pause more at the start of an intonation unit, which suggests that pausing is related to the speech-planning process (*see* **Pauses and Hesitations: Psycholinguistic Approach**).

Speech errors have also been studied by psycholinguists, who have classified them according to the assumed units of processing and types of mechanism involved in their production. For example, speech errors can relate to the phonemic features of the word, the syllabic structure, or the phrase or sentence being produced. This is illustrated in one of the famous errors reportedly produced by Dr Spooner in the 19th century when rebuking one of his students: 'you have tasted the whole worm' when he presumably intended to say 'you have wasted the whole term.' Here the initial phonemes are swapped but the rest of the morphemic and syntactic structure of the target utterance is preserved. Errors of this type became known as 'spoonerisms' as a result.

The kinds of error that occur can tell us a good deal about how speech is produced. Speech errors are very varied. They can reflect many different linguistic levels. Errors can involve the sounds of the words involved, for example saying 'the lust list' for 'the lush list.' They can relate to the intended words in a phrase, 'the pin of a head' being said in place of 'the head of a pin.' Errors may also focus on the semantic relations of the intended words, so a speaker may produce 'I like berries with my fruit' rather than 'I like berries with my cereal,' among many other forms of errors.

Some types of errors, however, do not occur and these patterns of occurrence and nonoccurrence have been used to help understand the speech production process. Content and function words are not substituted for one another and indeed substitute words are usually the same part of speech as the intended target word. When the wrong sound is produced, however, the substituted phoneme seems to have no grammatical relation with the intended target sound. The spacing between the errors is also informative for models of production. Errors of word substitution usually involve words that are a phrase apart. Yet sound errors seem to relate neighboring words. This sort of evidence has been used by several researchers to develop general models of the speech production process (*see* **Speech Errors: Psycholinguistic Approach** for more details).

Speech Recognition

Psycholinguists have also been concerned with exploring the processes involved in speech perception. Jusczyk and Luce (2002) summarized over 50 years of research on this topic. They described key research issues in the domain as understanding invariance, constancy, and perceptual units. In speech there are no invariant acoustic features that map directly to corresponding phonetic segments. The acoustic properties of sounds vary widely depending on the surrounding linguistic context. To make matters even more complex for the listener, there is also wide variability in the way phonetic segments are produced by different speakers depending on age, sex, and individual speaker characteristics. It is not even easy to determine what are the basic perceptual units that listeners use to recognize speech. Some research studies seem to suggest the phoneme as the basic building block of perception while others show advantages of the syllable over the phoneme. Conversational speech is therefore a very variable signal that does not even provide clear cues to boundaries between words. Yet understanding words in speech is an effortless and successful process for listeners with normal hearing. How is it done?

One of the key research challenges for psycholinguists was therefore to produce models of spoken word recognition. One of the most influential models is the Cohort Model (Marslen-Wilson and Welsh, 1978; Marslen-Wilson, 1989). In this account, when a listener hears an initial sound, all the words known to start with that sound become activated. This cohort of candidate words is gradually whittled down to a single word, as more acoustic information is processed and candidate words are eliminated. An important feature of the model is the uniqueness point. This occurs when the listener has heard enough acoustic information to reduce the cohort to a single candidate, i.e., there are no other words known to the listener with that particular sequence of phonemes. Syntactic and semantic context from the surrounding discourse can also play a role in rejecting potential candidate words. In later versions of the model, this can only occur after the uniqueness point, though in earlier versions, context could also be used to eliminate possible words before the uniqueness point. The

recognition point occurs when a single item remains in the cohort. This may be before the end of a word.

One of the strengths of the model is the way it can account for the speed with which spoken word recognition often occurs, often occurring before the word offset. In later versions of the model the activation of candidate words is a graded process. Candidate words are not completely eliminated as acoustic information accumulates, but rather they have their activation level reduced. This can rise again if later acoustic information matches a rejected candidate word. This is important, as one of the problems of conversational speech is that individual words or phonemes are often not articulated clearly and the listener must be able to recover and recognize words whose initial sounds were mispronounced or misheard in a noisy environment.

The main competitors to speech recognition models are various connectionist accounts, notably Trace (McLelland and Elman, 1986). This is a connectionist or parallel distributed processing (PDP) account of spoken language processing. In such models researchers were attempting to produce computational models of language processes which were inspired by what was known about the structure and processes of the human brain (*see* **Cognitive Science: Overview**). In spoken word recognition models, this meant that the feature units were simple units with dense series of interconnections, which processed by sending many messages in parallel. Such structures were developed as analogous to the neural architecture of the brain with its many nerves and interconnections.

The Trace model has three layers of units, corresponding at the lowest level to features, then at the next layer to individual phonemes, then at the top layer to complete words. All have dense arrays of interconnections between them, which like nerve pathways can be excitatory or inhibitory. The connections between levels are excitatory and connections within levels are inhibitory. Connections between levels operate in both directions, so both top-down and bottom-up processing can occur. The connectivity of Trace means that evidence is boosted and plausible hypotheses about the possible words emerge strongly. So a feature such as voicing will energize the voice feature units. These will then transmit activation to all the voiced phonemes at the phoneme level, which will in turn activate all the words that begin with these phonemes. At each level the activated units inhibit competitors at the same level, so reducing possible competitors. A word is recognized when in the end a single active unit remains.

Trace is a very interactive model. It gives context a bigger role in recognition than the cohort model. As a computational model it has the virtues of specificity. Trace models can be built and simulations run and then compared with the experimental data from human listeners. These comparisons have generally shown that Trace can cope with some of the problems of variability in production of features and phonemes, can account for the context effects on spoken word recognition that have been reported in the literature, and can cope with the kind of degraded acoustic input that is so typical of real conversational speech. The main criticisms that have been leveled at Trace concern the large role that context is given, which may be an overstatement of how this operates in human recognition. The other limitation is the less than elegant way that the time course of speech recognition is modeled, with duplication of the levels and nodes over successive time periods.

Other connectionist models have also been developed. Despite the competing architectures of the models, there is general agreement on key aspects of the speech recognition process. This involves activation of multiple candidate words, followed by competition among those known lexical items that share a similar sound profile; these processes have to be able to cope with less than ideal acoustic input and deliver perceptions of words very rapidly (for further details *see* **Speech Recognition: Psychology Approaches**).

Discourse Processing

The gradual broadening of the psycholinguistic research agenda has not been limited to the inclusion of speech alongside written language. Psycholinguists have also shown a growing interest in the processes involved in the interpretation not just of single sentences, but of complete texts. One of the first psychologists to explore the complexities of this process was Bartlett (1932). In his research on the way people remembered and reproduced stories that they had heard, he highlighted key research themes in discourse processing that are still current research topics. Bartlett noted how quickly the surface form of the story is lost and an individual's own interpretation of the text is what is remembered. He introduced the concept of a 'schema,' which was used when readers recalled a narrative. This consisted of an organized set of information based on prior experiences that is used in interpretation and recall. The interpretation of a narrative that is retained consists of a mix of input from the text and from schemata. In some of Bartlett's studies, British students listened to North American folktales. When asked to recall the stories accurately, strange narrative details relating to the activities of ghosts were unconsciously altered and supplemented

by details from the participants' world knowledge, so that the recalled version of the stories became more coherent by conventional Western standards.

More recently, a growing body of psycholinguistic research has been addressing the challenges of how readers build up a coherent mental representation to create a sense of the narrative world. One of the key concerns of psycholinguistic studies of text or discourse processing is the problem of inferences. Since Bartlett's seminal studies, it has been known that readers expand on what is in the text by drawing inferences based on their knowledge of the world. But what are the time course and limits of such inferencing? Many studies have been concerned with addressing such questions. Experimental studies have shown that some inferences seem to be made automatically **as** we read a text while some are made **later** to resolve apparent problems or inconsistencies. This was demonstrated in a study by Sanford and Garrod (1981), who presented readers with pairs of sentences such as the following:

(4a) Mary was dressing the baby.
(4b) The clothes were made of wool.

(5a) Mary was putting the clothes on the baby.
(5b) The clothes were made of wool.

The participants read the second sentence just as quickly in both cases. This suggests that verbs such as 'dress' cause readers to automatically draw the inference concerning 'clothes.' In contrast Haviland and Clark (1974) found that some inferences took a small but significant amount of time during reading. In their experiment they used pairs of sentences like the following:

(6a) Harry took the picnic things from the trunk.
(6b) The beer was warm.

(7a) Harry took the beer from the trunk.
(7b) The beer was warm.

They found that sentences like (6b) took longer to read than (7b), because the readers had to make the backward inference that the beer was part of the picnic supplies.

Researchers wished to determine the limits on the kinds of inferences which are made immediately and automatically and which are made later. Clearly, there must be limits on the amount of background knowledge readers activate and one of the research goals is to understand what these limits are and the cognitive processes which support this. Models have been developed that attempt to specify the way inferences are made and the way coherent mental representations are derived from texts. (For a fuller account of inferencing *see* **Coherence: Psycholinguistic Approach**).

Although there are significant differences between the models, there are several agreed features of how discourse processing operates in terms of the way readers update their mental representations of a text, the way some information is held in the foreground of processing while others is background, and the way that certain inferences are drawn automatically to maintain a coherent account of the text. For details of the various models of discourse processing that have been proposed (*see* **Discourse Processing**).

Reading as a Developmental and Educational Process

Before an interpretation of a written text can be made, the words on the page have to be read. Although apparently effortless for the skilled adult reader, the processes of identifying letters, recognizing words, and thus distinguishing the meaning conveyed in even a simple sentence, are complex. One key to unraveling how this is accomplished has been to study readers' eye movements. These have been shown to be very systematic and to consist of three main types: short forward movements of around 6–9 letters called saccades, which last on average 20–50 ms; backward movements called regressions; and the pauses or fixations when the readers' eyes rest on a word for around 250 ms.

Rayner and colleagues have shown there are consistent patterns in these movements (see e.g., Rayner, 1998). When reading more difficult texts, fixations grow longer, saccades grow shorter and regressions become more frequent. Even within a single text, readers will spend more time fixating relatively uncommon words compared to familiar ones. Eye movements are designed to keep the middle of our visual field, where our vision is best, aimed at new areas of interest. However, we are able to distinguish quite a lot of information within a single fixation. A skilled adult reader of English will usually be able to identify 15 letters to the right of the fixation point but only three or four letters to the left.

When children begin to learn to read they fixate words for longer than skilled readers. They also have a shorter perceptual span than adults, which means that in a single fixation they are able to identify fewer letters. Gradually these patterns approach those of adults as reading proficiency increases. The typical English reader's asymmetric perceptual span starts to appear in most young readers within a year of starting to learn to read. This seems to reflect the left-to-right nature of reading English, as readers of Hebrew, which is read right to left, show the opposite pattern in their perceptual spans. Like much of psycholinguistics, the study of skilled reading has largely

been the study of skilled English reading but more recently interesting studies have been conducted on other languages, notably on nonalphabetic scripts such as Chinese and Japanese. (*see* **Reading Processes in Adults** for more details).

Visual Word Recognition

One aspect of the reading process has received a great deal of research attention in psycholinguistics: the process of visual word recognition. A whole set of phenomena have been identified in the processes of recognizing written words. These include the process of priming. Words are recognized more quickly if they have been read previously. This is known as repetition priming. Words are also recognized more quickly if a word of similar meaning has just been presented, so 'butter' is recognized more quickly if 'bread' has just been read. This is known as semantic priming. Priming can also occur between words which do not seem to have a direct semantic relationship, such as 'music' and 'kidney,' which are linked by an intermediate word 'organ,' which was not presented to the readers.

Other phenomena which researchers have identified in word recognition include the fact that words which are common in the language, such as 'road,' are recognized more quickly than similar words that are less common, such as 'rend.' This word frequency effect is a strong influence on recognition speeds, with even fairly small differences in word frequency influencing reaction times. It is the most robust effect in studies of word recognition, appearing in many different studies using a wide variety of research methods.

These and other phenomena about how words are recognized have been used to develop a variety of models of word recognition. These can be grouped into families of related accounts. Some of the proposed models are direct access models, where perceptual information goes straight to feature counters or units. Other accounts propose that perceptual information is used to trigger a search through the mental lexicon, that is, the stored representation of all the words known to the reader.

One of the best-known serial search models was proposed by Forster (1976). In this account, the perceptual input is used to build a representation of the word to be recognized which is then checked in two stages by comparisons with a series of access files, which are analogous to the cards in a library index system. Once an input string is matched to an access file it is then linked to the master files, analogous to the books on the shelf, which contain the full lexical entries for each word. The files are organized to speed up the process of word recognition, with groups of files being arranged in bins that contain similar words. Within a bin, files are organized by word frequency. The details of the model are described to account for the observed features of the recognition process. For example, there are cross-references between master files that would support semantic priming. Despite these features it is not clear that this kind of serial search model can convincingly account for the speed with which words are recognized. It has also been criticized as being based on a rather dated analogy with the cognitive system as a digital computer rather than as a neural system.

Very recently, however, Murray and Forster (2004) have published an account of a series of word recognition studies that are claimed to show strong support for the serial search model. They claim that the structure within bins, notably the **rank** ordering of words within a bin in terms of frequency, accounts for the pattern of experimental results on word frequency effects more parsimoniously than alternative direct access models.

More popular models of word recognition involve direct access from the sensory information to the lexical units. One of the most influential of the early accounts of this sort was the Logogen Model (Morton, 1969). In this model, perceptual information, either from visual or auditory analysis, feeds directly into the logogen system. This consists of a series of units, logogens, which represent known words. Logogens act as feature counters and when a logogen has accumulated sufficient evidence to reach a threshold it fires. A word then becomes available to the output buffer, is recognized, and can be articulated. The logogens receive input from the cognitive system as well as the sensory input routes and so the resting threshold of the logogen can be varied by, for example, prior experience of a word, or from the sentence or discourse context. Common words with which an individual has had a lot of prior experience will have a lower threshold and will fire with less sensory input and hence be recognized more quickly. Similarly, words that are highly predictable from context will also have their thresholds raised and so will be recognized rapidly.

The Logogen Model has been used as the basis of computational models of word recognition, notably the interaction activation model (IAM) proposed by McLelland and Rumelhart (1981). This was one of the early connectionist or PDP accounts of language processing. Researchers were trying to produce computational models of language processes which were inspired by what was known about the structure and processes of the human brain (*see* **Cognitive Science: Overview**). In word recognition models, this meant that the feature units were simple units with dense series of interconnections, which processed by sending

many messages in parallel. The IAM consisted of three layers of units, corresponding at the lowest level to the visual features of letters, then at the next layer to individual letters, then at the top layer to complete words, all with dense arrays of interconnections between them, which like nerve pathways could be excitatory or inhibitory. The model was able to account for a wide range of experimental observations on word recognition. (For more details *see* **Word Recognition, Written**.)

Models of this type have become very widely used in psycholinguistics to explore a wide variety of language processes. This trend towards testing computational models against the existing experimental literature in a way that can link to new insights about the neural processes involved in language and cognitive processes is a popular approach in current psycholinguistics.

Dialogue and Gesture

In parallel to this concern with understanding the cognitive processes and the possible neurological architecture involved in language processing has been a growing interest in language processing in context. This means not only the growth in studies of how extended texts are processed but also a developing field of psycholinguistic studies of interactive language use. These studies have focused on language in its natural setting, interactive dialogue.

Dialogue represents the most ubiquitous form of language use. As young children, we learn to use language through dialogues with our parents and caregivers. Even educated adults spend a great deal of their time in conversations with family, friends, colleagues. Spoken dialogue is still used to obtain many forms of goods and services. In the many nonliterate cultures in the world dialogue is the main or only form of linguistic interaction.

Yet till recently dialogue received rather little research attention in psycholinguistics. One of the challenges for psycholinguists who wished to study dialogue was to derive methods of exploring the phenomenon which would produce testable and generalizable research questions and findings. One experimental method which has been used to allow the study of comparable dialogues from many pairs of speakers is the referential communication paradigm, developed by Krauss and Weinheimer (1964). In this, pairs of speakers are presented with an array of cards depicting abstract shapes. The speakers have to interact to determine which card a speaker is referring to at a given point in the dialogue. These early studies revealed key aspects of dialogue, including the way that over the course of a dialogue, the lengths of descriptions of even complex and abstract stimuli become much shorter and more concise. The interaction between the speakers was found to be crucial in this process. If this interaction was disrupted the speakers were not able to reduce their descriptions to the same extent.

Later studies on referential dialogues were conducted by Clark and colleagues. In one influential paper, Clark and Wilkes-Gibbs (1986) developed a collaborative model of dialogue. From studying many pairs of speakers engaged in dialogues, they highlighted the way speakers work together through their contributions to dialogue to arrive at a shared and mutual way of referring to things they wish to discuss. This means that the speaker and the listener both take responsibility for assuring that what has been said is mutually understood or 'grounded' before the dialogue proceeds.

In this view of dialogue, speakers follow the principle of collaborative effort and try to minimize their overall effort in arriving at an agreed description. This is done iteratively over a number of turns of speaking, often with each speaker contributing part of the description. This process makes use of the opportunities and limitations of spoken dialogue in a way that highlights its differences from written language. In text, the writer can take as much time as is needed to produce a description that she thinks the reader will understand. In dialogue, however, the speaker is under time pressure, as conversation rarely allows long gaps in which to plan an utterance. The speaker therefore has to produce an immediate description and may not be able to retrieve the most appropriate description or judge what way of describing a referent will be interpretable by the listener. The advantage of dialogue, however, is that the speaker and the listener can work together to refine or clarify the speaker's initial description till they both share a common understanding.

The highly collaborative nature of this process is reinforced in two key studies by Clark and colleagues. Clark and Schaefer (1987) showed how contributing to dialogue is characterized by two phases. Each time a speaker wishes to make a contribution, they produce a stretch of speech that is the content of what they wish to contribute. This is called the presentation phase. They then require an acceptance phase, in which their listener gives evidence of understanding the previous contribution. So the dialogue involves two activities: content specification and grounding, that is attempting to ensure that both speakers understand the content sufficiently for their current conversational purposes.

The importance of the ability to actively contribute to the dialogue interaction was demonstrated in a

study Schober and Clark (1989). Using the referential paradigm they had pairs of speakers complete the task. An additional participant was included in each interaction who overheard everything that was said but did not take part in the dialogue. This overhearer had a much harder time trying to identify the intended referents of the descriptions than the conversational participant, despite having the same pictures and having heard everything that was said. The suggested explanation is that the descriptions were not grounded for the overhearers. They had no chance to collaborate and ensure that they understood each description as it emerged during the dialogue.

So there is clear evidence that dialogue is an interactive and collaborative process that involves speakers and listeners attempting to cooperate and achieve mutual understanding. The detailed mechanisms that underpin these general processes of adaptation to the interlocutor are now the focus of a good deal of psycholinguistic study. There is some controversy over the extent to which speakers are able to adjust and adapt their output to their listener's needs. In terms of the forms of referring expressions chosen by speakers there is evidence of adjustment to the listener's general level of knowledge of the domain. When it comes to adjusting the intelligibility of their articulation, speakers seem to be largely egocentric. They reduce the clarity of their word production in terms of what is familiar to them as speakers rather than modeling their listeners' needs. The time course of adaptation is also debated, with some studies showing speakers initially produce utterances from their own perspective but later monitor their listeners and adapt. Other studies show listener adaptations from the start of speaking (for more details *see* **Dialogue and Interaction**).

As language processing is studied in more natural contexts of use, it becomes clear that speakers and listeners do not just communicate using the verbal channel. Visual signals from the mouth, face, hands, and eyes are all important features of communication. Researchers have begun to explore the way the visual channel is used by speakers and listeners and the relationship between verbal and visual signals.

More generally, in a dialogue, what we say, how much we say, and even the clarity of the way the words will be spoken have all been shown to change when speakers do or do not have access to visual signals. So speakers who can see one another need to say less to complete a task, use more gestures, can exchange turns of speaking more smoothly, and articulate their words less than when they cannot see one another.

The important role of visual signals in the perception of speech and how these are integrated with acoustic information is a fascinating research area. This was highlighted in a seminal study by McGurk and MacDonald (1976). They demonstrated that when a listener hears a phoneme such as 'ba' while watching a face mouthing 'ga,' the sound which is heard is a fusion 'da.' This is a powerful illusion that occurs even with knowledgeable listeners/viewers and has been demonstrated with young babies (*see* **Audio-visual Speech Processing**).

The role of visual signals in the production and comprehension of more extended stretches of discourse has also been the subject of considerable study. From studies of conversation and storytelling, the important role of gestures and their relationship to the accompanying speech has been established. For some kinds of gestures there is a close temporal relationship with the accompanying speech. Listeners also seem to fuse information presented visually and verbally. If they are told a story by a speaker who uses speech and gesture and are then asked to retell the story later, information originally presented by gesture, such as the speed of an action or the manner of leaving, is often relayed in speech and vice versa (for more information **Gesture and Communication**).

Future Directions in Psycholinguistics

Several trends seem apparent in psycholinguistics. Some of these seem to be the result of improvements and developments in the research methods available to psycholinguistics. One is an increased interest in detailed investigations of language in richer, more naturalistic, contexts. New research techniques such as improved methods of tracking a speaker or listener's eye movements mean, for example, that studies of dialogue, or the relationship of a speaker's production to the surrounding context, can be studied with the precision that used to be only possible in studies of isolated word recognition or sentence processing.

Improvements in the ease and accessibility of various brain-imaging techniques mean that these are being used not only as contribution to our understanding of the neural substrate of different language processes. Techniques such as ERP (event-related brain potentials) can now be used more and more as means to explore the precise time course of language processing. Newer techniques such as MEG (magneto-encephalography) are beginning to offer psycholinguists not just good information about the temporal patterns of language processing but also detailed information about the location of associated

brain activity. (For more information *see* **Psycholinguistic Research Methods**.) The growing interest in the neural substrates which support language processing has received a major boost from the development of these new forms of brain imaging.

The interest in how to build neurologically plausible models was of course one of the drivers behind the expansion over the last 20 years in connectionist models of language. These have made a major contribution to our understanding of how a wide variety of language processes, such as spoken or written word recognition, might operate and be learned. The challenge in the future will be to see whether connectionist models can be implemented for more extensive language processing, such as text comprehension or contribution to dialogues. The way such models can or cannot be scaled up to simulate more complex language processing will be one of the key challenges for the next few years.

In the future psycholinguistics will also need to address its undoubted Anglocentric bias. The vast majority of studies of language processing are in fact studies of English language processing. In a number of areas a few studies are emerging which consider other languages but this effort needs to be greatly increased. Over the last 50 years psycholinguistics has expanded dramatically and made considerable progress in understanding a wide variety of language processes. With new research techniques and a more balanced research portfolio in terms of the languages studied and the research efforts applied to production as well as comprehension, spoken as well as written language, future progress seems assured.

Psychosis and Language

M Simard, Université Laval, Québec City, Canada

Several psychiatric disorders are included under the broad definition of psychosis. The most common disorders are schizophrenia (which is prototypical of the psychoses), schizophreniform disorder, schizoaffective disorder, and delusional disorder (APA, 1994). These other psychotic disorders share some distinctive features with schizophrenia (e.g., a schizoaffective disorder is a disturbance in which a mood episode and characteristic symptoms of schizophrenia occur together). Furthermore, an array of psychiatric and medical conditions also presents with psychotic attributes and is often characterized by presenting typical symptoms of schizophrenia.

The contemporary consensual definitions of schizophrenia and most common psychotic disorders of the *Diagnostic and statistical manual* have resulted from more than 100 years of conceptual work. The current criteria for schizophrenia derive from the early works of Emil Kraepelin (1899), Eugen Bleuler (1911), and Kurt Schneider (1957).

Background History of the Contemporary Diagnostic Criteria for Schizophrenia, Autism, and Asperger's Syndrome

Emil Kraepelin meticulously described the symptoms of schizophrenia, which he named *dementia praecox*, referring to the disruption of emotional and cognitive features as well as to the deteriorating course of the disorder. He also tentatively proposed a pathophysiological localization, suggesting that abnormalities in the frontal lobe would be the substrate of problems with reasoning and volition, whereas abnormalities in the temporal lobe would be the substrate of delusions and hallucinations (Kraepelin, 1899).

In his conception of schizophrenia, Eugen Bleuler emphasized the importance of a formal thought disorder (disorder of associations or 'splitting'). To overcome the limitations of Bleuler's approach in the observation of the disorder, the concept of thought disorder was transformed into problems of language and communication behavior in the work of Andreasen (1979) and into disorganized speech in the criteria for schizophrenia in the *Diagnostic and statistical manual of mental disorders* (4th edition) (DSM-IV) (APA, 1994).

In the mid-20th century, Kurt Schneider (1957) described the primary disorders of the experience of thought representing the current core features of the positive symptoms. This characterization is known as the Schneiderian First-Rank symptoms, which include hearing voices speaking one's thoughts aloud, hearing voices arguing about oneself, hearing voices commenting on one's actions as they are occurring, having bodily sensations imposed from outside, attributing one's feelings to external sources, experiencing one's drives as originating from powerful outside forces, moving and acting as a result of external controls, having one's thoughts withdrawn from the mind, having one's thoughts inserted into one's mind, broadcasting of thoughts, and attributing special personal significance to one's perceptions. Schneider's symptoms were thought to be pathognomonic signs, any of which was strongly indicative of a schizophrenic disorder.

Psychosis is not a unitary concept. The 'psychotic' designation is often applied to symptom presentation that may vary considerably, both biologically and behaviorally. The wide variety of psychiatric and medical conditions that present with 'psychotic' features attests to the heterogeneity of psychotic disorders. It is now recognized that schizophrenia is at least clinically a heterogeneous disorder (Ragland, 2003), and this characteristic necessarily has an impact on the presentation of language and speech impairments that may arise from that condition.

The heterogeneity of autism is also so well acknowledged (Eigsti and Shapiro, 2003) that the term autistic spectrum disorder (Rapin and Dunn, 2003) is frequently used to describe the different extents of severe functional deficits in sociability, communicative language, imaginative play, and range of interests that principally characterize this condition as per the DSM-IV (APA, 1994).

Background History of the Contemporary Diagnostic Criteria for Schizophrenia, Autism, and Asperger's Syndrome

Emil Kraepelin meticulously described the symptoms of schizophrenia, which he named *dementia praecox*, referring to the disruption of emotional and cognitive features as well as to the deteriorating course of the disorder. He also tentatively proposed a pathophysiological localization, suggesting that abnormalities in the frontal lobe would be the substrate of problems with reasoning and volition, whereas abnormalities in the temporal lobe would be the substrate of delusions and hallucinations (Kraepelin, 1899).

In his conception of schizophrenia, Eugen Bleuler emphasized the importance of a formal thought disorder (disorder of associations or 'splitting'). To overcome the limitations of Bleuler's approach in the observation of the disorder, the concept of thought disorder was transformed into problems of language and communication behavior in the work of Andreasen (1979) and into disorganized speech in the criteria for schizophrenia in the *Diagnostic and statistical manual of mental disorders* (4th edition) (DSM-IV) (APA, 1994).

In the mid-20th century, Kurt Schneider (1957) described the primary disorders of the experience of thought representing the current core features of the positive symptoms. This characterization is known as the Schneiderian First-Rank symptoms, which include hearing voices speaking one's thoughts aloud, hearing voices arguing about oneself, hearing voices commenting on one's actions as they are occurring, having bodily sensations imposed from outside, attributing one's feelings to external sources, experiencing one's drives as originating from powerful outside forces, moving and acting as a result of external controls, having one's thoughts withdrawn from the mind, having one's thoughts inserted into one's mind, broadcasting of thoughts, and attributing special personal significance to one's perceptions. Schneider's symptoms were thought to be pathognomonic signs, any of which was strongly indicative of a schizophrenic disorder.

Psychosis is not a unitary concept. The 'psychotic' designation is often applied to symptom presentation that may vary considerably, both biologically and behaviorally. The wide variety of psychiatric and medical conditions that present with 'psychotic' features attests to the heterogeneity of psychotic disorders. It is now recognized that schizophrenia is at least clinically a heterogeneous disorder (Ragland, 2003), and this characteristic necessarily has an impact on the presentation of language and speech impairments that may arise from that condition.

The heterogeneity of autism is also so well acknowledged (Eigsti and Shapiro, 2003) that the term autistic spectrum disorder (Rapin and Dunn, 2003) is frequently used to describe the different extents of severe functional deficits in sociability, communicative language, imaginative play, and range of interests that principally characterize this condition as per the DSM-IV (APA, 1994).

Asperger's syndrome (AS) is a less severe syndrome of the autistic spectrum disorder, presenting with repetitive and stereotyped behaviors and severely altering social interactions (APA, 1994). As opposed to autism, there is no developmental delay in language in early childhood (DSM-IV). Nonetheless, communication abnormalities do exist in this condition (Frith, 2004; Rapin and Dunn, 2003).

Language Impairment in Schizophrenia, Autism, and Asperger's Syndrome (Neurodevelopmental Psychotic Disorders)

DeLisi (2001) reported in a review of English literature on language and speech disorders in adults with schizophrenia that several aspects of language comprehension and production were impaired in patients with chronic schizophrenia compared to patients with bipolar psychosis, their nonpsychotic siblings, or controls. Patients with schizophrenia had problems with speech comprehension, semantics (misuse and misrepresentations of words, and neologisms), syntactic complexity (only with speech), and language lateralization, and they demonstrated a paucity of speech, reduced verbal fluency, reference failures (i.e., when the speaker incorrectly infers that what he or she is referring to has been clearly stated), personal disorganization, and social alienation. They also produced more intrusions and showed a hyperpriming effect in lexical and semantic priming task paradigms (DeLisi, 2001). A recent meta-analysis involving 13 studies confirmed the impairment of verbal fluency and further showed that semantic fluency was significantly more disrupted than lexical fluency in patients with schizophrenia (Bokat and Goldberg, 2003).

Early studies examining language in verbal children on the autistic spectrum described speech abnormalities such as unusual word choices, pronoun reversal, echolalia, incoherent discourse, unresponsiveness to questions, aberrant prosody, and lack of drive to communicate. Persistent lack of speech in some individuals was attributed to the severity of their autism and mental retardation rather than the possible inability to decode auditory language. More recent clinical studies of unselected children with autism demonstrated that language deficits of preschoolers can be divided into two types: those that involve reception and production of phonology and syntax, and those that involve semantics and pragmatics (Rapin and Dunn, 2003).

The vocabulary of children later diagnosed with Asperger's syndrome is generally described as precociously adult, containing words not normally used by children (Frith, 2004). Adolescents and adults with AS have been found to show more pragmatic problematic responses in interactional conversation than the control group (Adams *et al.*, 2002; Frith, 2004), and adults with AS have been found to show a preference for written over spoken communication (Frith, 2004).

The Neuropsychological Model

Different explanatory approaches were proposed over the years with regard to the disorders of speech and language in schizophrenia and autistic spectrum disorders. In the first approach or the neuropsychological model, the disturbances in speech and language are caused by a cognitive impairment in schizophrenia other than language, such as deficits of attention and working memory (Thomas *et al.*, 1996; Tracy, 1998), of initiation, planning, and self-monitoring of action (Frith and Done, 1988; Kircher and Leube, 2003), of organization of information (Ragland *et al.*, 2003), and of the 'theory of mind' (TOM) (Frith, 1994; Sarfati, 2000). All of these cognitive impairments are consistent with a frontotemporal dysfunction central to the neurodevelopmental disorder hypothesis suggested by Weinberger (1987) with regard to the origin of schizophrenia.

The impairment of speech comprehension, reference failures, and decreased syntactic complexity of speech were found particularly related to working memory and attention problems in schizophrenia (Thomas *et al.*, 1996; for reviews, see DeLisi, 2001; and Tracy, 1998). Frith (1994), on the other hand, suggested that many signs and symptoms of schizophrenia can be explained by an alteration of processes underlying the TOM. According to this hypothesis, patients with schizophrenia would lack the ability to represent beliefs and intentions, i.e., other people's mental states. This deficit would translate into difficulties in social relations and communications, and into stereotyped behaviors. Paranoid delusions and auditory hallucinations would thus be the consequences of this problem of attribution of intentions and inferences (Frith, 1994). Several recent studies demonstrated the inability to represent intentions and beliefs that were inserted in indirect speech or scenarios, as well as the inability to understand humor (especially mental jokes), in individuals with schizophrenia. Patients with persecution and reference delusions, hallucinations, and negative symptoms as well as having paucity and incoherence of speech were significantly more impaired on these TOM paradigms than patients with passive ideas, those in remission, and controls (for a review, see Sarfati, 2000; Pickup and Frith, 2001). However, the alterations of the theory of mind have been

found to be less severe in schizophrenia than in autism (Pickup and Frith, 2001).

Individuals with autism and Asperger's syndrome were found to be particularly impaired on TOM tasks, and these deficits were related to their severe difficulties with pragmatic speech and communication (Frith, 2004; Martin and McDonald, 2003). However, these findings remain controversial (Martin and McDonald, 2003).

The Connectionist Model

In the second explanatory approach, the authors following the 'Bleulerian' tradition of thought disorder studied alterations in the semantic networks using a connectionist model with the event-related potentials (ERP) N400 (for reviews, see Kumar and Debruille, 2004; McCarley *et al.*, 1999). Connectionism usually represents words as networks of interconnected nodes. Whereas previous connectionist models assumed one-to-one representation between a word and a node, current distributed models of representation involve various aspects of words such as the orthographic, semantic, and phonological components, each represented by corresponding sets of nodes. The principal feature of nodes is that they are organized into local networks and activated in parallel such that a word activates (or primes) a local network of related associates. Cued-recall word paradigm studies showed that subjects with schizophrenia present with an overactivation of strongly connected semantic networks and an underactivation of weakly connected semantic networks, whereas the size of semantic networks is normal. Thus, this connectivity abnormality is likely to be a preferential processing of the strongest (dominant) association, with the neglect of preceding contextual information (see McCarley *et al.*, 1999, for a review). These findings are supported by the results of research using lexical and semantic priming, which have built up considerable evidence suggesting that schizophrenia thought intrusions and derailments in discourse arise from the hyperactive functioning of semantic networks or 'hyperpriming' (for reviews, see Kumar and Debruille, 2004; McCarley *et al.*, 1999; Tracy, 1998), especially during the acute psychotic state (Gouzoulis-Mayfrank *et al.*, 2003).

The data gathered at the level of functional neural systems using the ERP N400 confirmed the previous findings. The N400 is a negative waveform that develops between 300 and 500 ms after word onset. All meaningful words elicit an N400, and the amplitude of this waveform is usually much greater in response to words that are unexpected in a given context. It is thus hypothesized to reflect processes involved in contextual integration, which is a central feature of language comprehension (Kumar and Debruille, 2004). Patients with schizophrenia and schizotypical personality disorder demonstrated significantly reduced N400 amplitude, when compared to controls, to the target words that were related or associatively linked with the first words in word-pair lexical decision tasks. These data corroborated the overactivation of strongly connected semantic networks (McCarley *et al.*, 1999). In addition, many studies have documented N400 evidence supporting contextual abnormalities in schizophrenia (Kumar and Debruille, 2004; McCarley *et al.*, 1999), and preliminary evidence suggests the same abnormalities in autism (Rapin and Dunn, 2003).

The Evolutionary Model

In the third approach, the evolutionary model, a disturbance in the uniquely human aspects of language, following the failure of hemispheric dominance for language, is central to the genetic etiology and clinical presentation of schizophrenia (Berlim *et al.*, 2003; Crow, 1997; DeLisi, 2001). Crow especially hypothesized that an anomaly in the sex chromosomes (protocadherin XY in the Xq21.3/Yp region of homology) is the origin of the lack of brain asymmetry in schizophrenia (Crow, 1997; Berlim *et al.*, 2003). In support of this theory, the First-Rank Symptoms (FRS) symptoms were positively correlated with speech disorder and loss of normal cerebral asymmetry as measured by reduced right-hand preference in patients with schizophrenia (Ceccherini-Nelli and Crow, 2003; Verdoux *et al.*, 2004). However, the failure to find genetic linkage for psychosis on chromosome X tends to invalidate the theory (see Berlim *et al.*, 2003, for a review).

Conclusion

A number of explanatory models may be mandatory to understand the mechanisms of speech and language disorder in schizophrenia since it has a heterogeneous clinical presentation (Ragland, 2003) for which several subtypes of language impairment may exist.

In autism, social and cognitive disorders alone cannot provide an appropriate explanation for the range of language deficits, since pure linguistic problems (semantics, comprehension, and production of phonology and syntax) seem to exist with a pathophysiological substrate (Rapin and Dunn, 2003). Only in the case of Asperger's syndrome does the neuropsychological model of an alteration of the theory of mind seem somehow to explain the pragmatic language impairment to a more satisfying degree. However, data on this particular topic remain controversial and thus require replication (Martin and McDonald, 2003).

Psychotherapy and Counselling

S Vehviläinen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Psychotherapy, the talking cure, aims at restoring the client's mental health and solving problems of identity, personality, relationships, and mental well-being. Its cognate practice, counseling, is seen by many to essentially aim at the same: "both activities aim to alleviate human suffering, solve problems, and help people live a more satisfying life" (Dryden and Feltham, 1996: 2; cf. Feltham, 1995). The practices of therapy and counseling, and the related activities and processes, happen via discourse. They are based on complex institutional arrangements and processes and are informed by concepts and theories of the human mind, relationships, and social problems, as well as philosophies of the human condition and various rules and ideals regarding the appropriate practices through which solutions to problems can be found. Whichever ways these arrangements, concepts, and ideals guide the actual practices of the talking cure, it necessarily, and usually solely, takes place via particularities of talk and interaction between clients and institutional helpers.

Due to the deep connectedness of psychotherapy to talk and interaction, measurement of the outcome of therapies is met with great methodological problems. The definitions of mental problems and recovery differ in different therapies, and problems are caused by the effect of the competence and other personal qualities of the therapist and from the difficulty in eliminating the placebo effect. It has been claimed that the effects of therapy can be offered by any sympathetic recipient. Even researchers that do not take this extreme view have pointed out that the interaction between the participants of therapy and the match between them are essential in terms of the outcome of psychotherapy. Therapeutic help, then, necessarily relies on resources of mundane interaction. The talking cure may occur, not only within therapeutic institutions, but also between laypersons, in friendships, in families, and in institutional encounters at the fringes of the therapeutic institutions. At issue is what constitutes therapeutic help as a particular kind of discourse and how therapeutic interventions are carried out as achievements of language use and interaction (*see also* **Social Construction and Language**; and **Institutional Talk**).

Since Freud started his work of psychoanalysis, case studies have been a central approach for understanding the process of therapeutic help. Seminal studies of language and interaction in therapy are also based on case studies – in-depth analyses of single sessions – but unlike Freud, whose cases were based on the analyst's postencounter accounts, studies of discourse make use of recordings of therapeutic encounters. Labov's and Fanshel's (1977; *see* **Labov, William (b. 1927)**) 'comprehensive discourse analysis' presented an overall synthesis of a recorded therapy session between 'Rhoda,' an anorectic young woman, and her therapist. Combining the analysis of speech acts and paralinguistic features within topical episodes, the authors 'expanded the text' of what is actually said in the tapes, using their own understanding of the entire session and of the speaker's intentions, as well as the therapist's playback comments. As a result, they provided a detailed reading of what actions are performed in the therapy session and how the therapist works with the client's resistance and mitigation of her 'true' feelings. This book is a seminal work as an application of linguistic discourse analysis to therapeutic discourse, and it presents a comprehensive arsenal of linguistic categories for observing discourse.

Empirical research on interaction and language in therapy and counseling has since the 1970s profited from another type of research setting, namely, that of accumulating empirical observations of linguistic resources and interactional patterns, systematically used by practitioners and their clients when carrying out therapeutic or counseling tasks. Such an approach to the empirical, observation-based study of interaction, used in conversation analytic research (Drew and Heritage, 1992; *see* **Conversation Analysis**; **Conversational Analytic Approaches to Culture**; **Medical Discourse: Doctor–Patient Communication**; and **Ethnomethodology**), has identified various systematic patterns, linguistic or interactional resources and devices in a number of encounters, thus rendering them comparable within and across settings. From such a point of view, the approach in Labov's and Fanshel's study is problematic (Levinson, 1994; Potter, 1998). The main argument in conversation analysis, adopted also in some recent versions of discourse analysis (Edwards and Potter, 1992; *see* **Critical Discourse Analysis**), is that interaction should be observed as it unfolds, in real time, and that the analyst of discourse or talk should examine the resources and devices that the participants use and make public to understand each other in a turn-by-turn fashion. Thus, instead of expanding the transcribed talk by attempts to read into the analysis the intentions or emotional states of the speakers, one should examine the way that participants design their turns of talk in the interaction and treat these moves as selections that reveal speakers' social

orientations both to the action and to the setting at hand (*see* **Meaning, Procedural and Conceptual**).

Since Labov's and Fanshel's work, there has been an expansion in the study of language and interaction in institutional settings. Psychotherapy and counseling as forms of the 'talking cure' have become more diverse, and an increasing interest has emerged in the empirical study of interaction also within psychotherapy process research (Siegfried, 1995). Conversation and discourse analytical research in social sciences and linguistics has increased knowledge of how patterns of interaction and linguistic resources construct institutional encounters between providers of therapeutic help and their clients and how therapeutic or counseling aims and related ideologies are 'talked alive' in interaction (Peräkylä, 1995; Morris and Chenail, 1995; Silverman, 1997; Arminen, 1998). The results of this research can be grouped under four central themes, the first of which focuses on the way in which help-seekers talk about their problems, and the other three deal with interactional devices used by the professionals.

Descriptions and Stories of Troubles

Psychotherapies, as well as many forms of counseling, are based on the clients' narratives of themselves and their lives. The starting point of the encounter – and a series of encounters – is how the client understands her or his life and problems. The problems that clients bring to the helpers are presented and shaped into shared objects of action, first by the clients' narratives. Harvey Sacks, the founder of conversation analysis, noted in one his lectures how we routinely identify distinct, institutional forms of discourse by comparing them to mundane practices. He quoted Freida Fromm-Reichmann's recommendation to the good psychiatrist: to become one, one must learn to listen to the patient carefully and to not be reminded of one's own experience in the process (Sacks, 1995: Vol. I, 764–772; *see* **Sacks, Harvey (1935–1975)**). Sacks noted how listening to another speaker – the social demonstration of listening – in everyday conversation is, actually, characterized by the very opposite of this rule. We show that we are listening, and hearing the appropriate moral relevancies of the story, by the very kind of second (occasioned, touched-off) stories we choose to tell.

A form of therapy that is completely based on storytelling, narrative, and this kind of 'demonstrated' understanding is the mutual help in Alcoholics Anonymous (AA). The sharing of monological stories and responding to others' stories through 'second stories' (i.e., narratives that are presented as occasioned by prior stories and demonstrate similarity to them) constitute the essential interactional resource by which the recovery from alcoholism (or other addictions) is accomplished (Arminen, 1998). Sharing of personal stories, thus, constitutes the therapeutic device and practice. In the openings of the monological contributions in an AA meeting, there is a strong tendency to refer to other speakers' contributions and thereby to show that one's topic is occasioned by a previous speaker's topic. Claiming similarity of experience, and demonstrating this similarity through providing an occasioned story, are therapeutic practices by which AA members share their experiences, maintain sobriety, and construct their identities as recovering alcoholics.

Arminen's study also provides for the way in which the distinct, formal turn-taking order (1998: 49–79) is oriented to and maintained by the participants and how that too becomes the vehicle for therapeutic sharing. In the formal turn-taking order of AA, each speaker is entitled to one monological turn that is supposed to be about one's own experience, and other speaker's turns are not countered or challenged. This format, with some variation, is known also in group therapy settings where the participants orient to the expectation to share and identify with one another's experiences, although in settings where a professional is involved, he or she typically has different speaking rights than the clients.

AA monologues are biographical descriptions about alcoholism, finding mutual help in AA, and maintaining sobriety. They are narratives that are presented from the speaker's perspective and about the speaker's personal experience. References to other speakers are used so as to indicate sharedness of experience, and disagreements between speakers are subtly embedded into these references without overt countering. Edwards's (1995) analysis on talk in couples counseling provides a very different angle to the way in which client's talk is constructed for particular therapeutic purposes. He showed how clients talk about relationship troubles (couples speaking about each other in each other's presence), presenting overtly disagreeing versions of their troubles to the counselor, whose task it is to receive these versions impartially in order to find solutions to the problems. Edwards first identified a number of linguistic resources by which the speaker may describe another's person's action as 'scripted,' that is, as stemming from a routine that reveals that person's dispositions. He also showed how couples design these descriptions, or blamings, so that they carefully attend to their partner's counterdescriptions. Thus, as Edwards pointed out, they are very much aware of each other's countering versions and design their own versions so as to undermine them and defend their own version.

There is a 'rhetorical symmetry' between countering versions of relationship troubles: Jack is portrayed as 'jealous,' whereas Jill is portrayed as 'flirty.'

Asymmetries in Therapeutic Discourse

One of the major sources for asymmetry – i.e., systematically different speaking rights of different participants – in institutional interaction is that, typically, it is the professional that determines the agenda for the encounter, though it may remain opaque for the client. Therefore, it is often a shared orientation of both participants that the professional will guide the client along the agenda, ask relevant questions, and draw proper conclusions about the material the client provides, with respect to the therapeutic approach at hand. Thus, in classical psychoanalysis, the patient's talk is listened to as containing layered meanings: the associative links, slips of tongue, contradictory elements, dreams, and other such features, conveyed in talk, are treated as revealing to the analyst evidence of the patient's unconscious conflicts, which constitute relevant foci for therapeutic work. On the other hand, a solution-focused brief therapist would listen to the clients' talk, searching mainly for cues to practical solutions and avoiding focusing on the problems or their reasons.

Asymmetry in tasks and speaking rights is tightly intertwined with differing access to knowledge. Only the clients know what they experience. On the other hand, the therapist is the expert on how one might become cured or healed – how one may come to feel or function better. It is the client's mind and experience that is the focus of both participants' attention. Labov and Fanshel (1977) introduced a distinction based on the relationship between a description of a state of affairs and the kind of knowledge participants are taken to have of it. Thus, an A event is biographical or experiential information of the speaker's that he or she has privileged access to, while others do not. A B event is a description of a matter of another speaker's experience or life, and the speaker thereby has limited access to it. This is a crucial distinction in therapeutic and counseling discourse and a widely quoted concept even outside Labov's and Fanshel's own approach. It has proved to be a central analytic dimension also for conversation analysts, under the title of 'ownership of experience' (Peräkylä and Silverman, 1991). Although the clients are in the authoritative position toward their own experience, the therapists or counselors construct interpretations in which they typically attempt to reshape the meaning of these experiences and renegotiate the nature of the clients' problems. Thus, the talking cure is necessarily characterized by clients' talk on A events, whereas therapists and counselors must often address B events in their talk.

As Jörg Bergmann (1992; *see also* **Medical Discourse: Psychiatric Interviews**) has pointed out, in the practice of treating mental problems, morality and medicine become intertwined. Treating or easing mental pain involves medical aspects of diagnosis, symptoms, and cure, as well as social and existential issues of what constitutes a good life, a sustainable and respectable social identity, and good life choices. Bergmann analyzes psychiatric discretion and various 'discreetly exploring utterances': fishing for information rather than asking directly, using 'litotes' expressions ('running around not so completely dressed' vs. 'running around naked'), mitigators, and euphemisms. These are viewed as practices of discreet exploration.

However, demonstrations of discretion also mark the delicately approached issue as a difficult and morally loaded one. Thus, devices of discreet talk elicitation that offer the floor for the client to talk about her or his problems and express her or his concerns are the very same devices that hint that issues that need to be approached so delicately are necessarily socially difficult ones. Responding to such elicitations leads the client to talk under the auspices of such 'veiled morality,' and as Bergmann showed, not all psychiatric patients are willing to do this. "Discreetly exploring utterances are extremely vulnerable to being heard by the recipient in moral terms and may therefore trigger uncontrollable, interactionally disastrous social situations" (Bergmann, 1992: 157).

One of the most studied conversational phenomena in therapeutic discourse is the professional's formulation of the client's talk. Heritage and Watson (1979) studied how speakers can display an understanding of what has been said in the prior talk or what has been accomplished through the talk. In a formulation, the speaker explicates, paraphrases, or summarizes what the prior talk has meant or amounted to, presenting a gist or an upshot of it. As it suggests the meaning of another person's talk, it calls for a reaction from that person, who has the privilege to confirm or reject the formulation. Furthermore, formulations always transform what has been said, selecting some aspects and deleting others. This makes formulations interesting in terms of institutional talk, where the work of summarizing and transforming the prior talk is carried out for particular, institutional reasons. The professional performs actions through which institutional agendas – institutional tasks and institutional reasoning – are implemented.

Hak and DeBoer (1996) suggested that formulations can 'democratize' institutional interaction, since it is through them that the professional can show the

client some of the reasoning that guides the procession along the agenda and thereby avoid a hidden agenda. Formulations have also been examined as a device for professional power. They can be used to shape the therapy client's initial trouble descriptions toward a 'treatable' or 'therapeutically relevant' problem. In a case study of a single first session, Kathy Davis (1986) made a much cited statement about the professional power used by the therapist. She pointed out that the therapeutic reformulation, arrived at during the first encounter at the beginning of therapy, was the result of a wealth of work on the therapist's part. Davis showed how the therapist formulated the patient's talk as evidence of a particular kind of behavior, made this behavior the focus of the talk, and repeatedly offered it to the client. Davis's feminist reading of the (male) therapist's individualization of the (female) client's problems – instead of contextualizing her problems socially – highlights the salience of this conversational device to the implementation of institutional agendas (*see* **Gender and Language**). Therapists' formulations are rich in 'institutional flavor.'

Formulations are also used to deliver the professional's evaluations, conclusions, or 'diagnostic' understandings of the client's situation. Couples counselors use what Derek Edwards (1995) called script formulations. They formulate a couples' situation in ways that treat the participants as having expressed their true concerns, avoiding placing the blame on either of the clients alone and showing that their trouble is, itself, scripted: a pattern that affects both parties and one that can be dismantled and for which a solution can be sought. Alternatively, in classical psychoanalysis, formulation is one of the conversational formats by which psychoanalytic interpretations are prepared for and delivered (Vehviläinen, 2003; *see* **Psychoanalysis and Language**). The analyst may use formulations to imply that what he or she claims about the patient is essentially based on what the patient her- or himself has said, while adding to it material that originates from another context. Thus, the analyst is able to, for instance, combine materials of a dream and its 'associations' (i.e., tellings occasioned by it) and imply that together these materials reveal an underlying (unconscious) pattern of the patient's mind. Formulations, then, serve as a device for reading unconscious content into the patient's talk and presenting this 'reading' to the patient.

Most professionals in institutional professional–client encounters, in fact, exercise the 'formulating power' – the power to draw conclusions about the material elicited from the client and to make these conclusions 'stand for the record' in the interaction. What is unique to therapeutic settings is the professional's power to read into the patient's talk a 'subtext' – often with reference to the unconscious layers of the client's mind (Peräkylä, 2004).

'Determining Who the Client Is' as the Counselor's Institutional Task

Psychotherapy may be viewed as a form of 'facilitated introspection,' resulting in a new reading of the client's situation and experience. Counseling – sharing essentially the same aims of helping and easing suffering – usually aims at dealing with more practical and clear-cut problems, transitions, crises, or choices, such as career, unemployment, or illness issues. Furthermore, depending on the institution that provides the counseling, the professional will typically orient to other aims than mere facilitation of introspection or self-reflection, for instance, influencing the matching of student counselees with appropriate subjects of study in college counseling, delivery of information or advice on safe sex, finding realistic solutions to unemployment, or promoting university students' self-directedness.

In many counseling settings, such as college counseling, the counselor's tasks involve categorizing work with respect to who the client is. The process of determining the counselee's institutional identity ('an Asian female math major'), then, has consequences for how the counseling process proceeds. Various studies have been conducted on encounters in college and university counseling in the United States, examining how identities are maintained and created in the counseling encounter – not only those of the counselor and the counselee, but also other social identities, such as gender and ethnic identities or academic identities such as 'math major.' In this setting, constructions of 'who the student (client) is' may have particular consequentiality in terms of the outcome of the counseling.

Erickson's and Schultz's (1982; *see also* **Interactional Sociolinguistics; Critical Applied Linguistics; Cultural and Social Dimension of Spoken Discourse;** and **Communicative Competence**) seminal microethnography of American college counseling suggested that college counselors have a gatekeeping role: along with advice, they can also "grant or withhold permission for the student to enter or continue a particular course of study" (Erickson and Schultz, 1982: 20). Erickson and Shultz pointed out that the counselor's work is essentially about defining, through the counseling interview, who the student is. The study used videotapes of encounters along with participants' commentaries on the tapes. The authors studied various phenomena such as verbal and nonverbal contextualizing cues or the rhythm of speech, identifying

several interactional features that are likely to affect the way that individuals experience one another and their encounter, and the ways in which these experiences are related to the social (especially ethnic or speech community) identities of the participants (*see also* **Doctors and Patients in Multilingual Settings**). One of their main arguments was that communication styles, and situationally defined comembership in a social category (speech community or other), have consequences for the friendliness of the encounter and the amount of personal attention and help that the student receives (see also He, 1995; *see* **Speech Community**; and **Identity and Language**). These studies provided evidence that college counseling, indeed, functions as a gatekeeping activity, in addition to facilitating and becoming an advocate for the student's own aspirations. They also showed that the local management of social identities – ethnicity and various locally invoked comemberships – influences the counselor's gatekeeping and the outcome of counseling.

The Ownership of Experience, Professional's View, and Client-Centeredness

Another important set of counseling studies deals with HIV or AIDS counseling and guidance in Great Britain and the United States (Peräkylä, 1995; Silverman, 1997; Kinnell and Maynard, 1996). In HIV counseling, the aim is to deliver information about HIV and AIDS, to advise people about safe sex, and, thus, to prevent transmission of HIV. Furthermore, the purpose of counseling is also to help people cope with their HIV- or AIDS-related fears and problems. Due to this double function, the issue of expert knowledge has a central role, but there is also a concern over how to create a space for the client's perspective and how to design the interaction so as best to serve the client in whatever situation he or she is in. The overarching themes in these studies are talk elicitation and dilemmas of advice giving.

The talking cures rest on the clients' descriptions of how they view their experience and problems. The core task of therapists and counselors, therefore, is to elicit such descriptions from the client. The practical concern is to engage clients in talk about their own lives, from their own perspective, and often about delicate issues such as sexual behavior or fears connected with HIV. Discreet exploration, studied by Bergmann (1992) in the context of psychiatric interviews, is prominent in many counseling settings and reported by many researchers. Devices of professional caution are typically used so as to downgrade the epistemological status of descriptions of issues that are 'owned' by the recipient. This means that professionals speak cautiously and tentatively on matters that concern the client's experience and display in their talk that their knowledge is not authoritative.

Peräkylä and Silverman (1991; Peräkylä, 1995) have examined this issue in a setting in which counseling involves not only clients but also their partners or family members. These counselors have adopted the 'Milan School Family Systems Theory,' which is a therapeutic theory about individuals and their problems as located in networks of relationships or 'family systems.' The counselors use a particular interviewing technique to engage clients and their significant others in discussions about various issues. The authors show how all participants orient to the particular relationship that persons have to those experiences they 'own' (Peräkylä and Silverman, 1991) and how counselors use particular techniques to invoke ownership of experience and thus elicit client talk (Peräkylä, 1995).

In circular questioning, used in family systems therapy, one of the clients is asked to describe the experience of another. Peräkylä, who has studied the interactional dynamics of implementation of this practice in HIV counseling, showed that both clients and counselors orient to the owner of the experience having the privileged participation status and authoritative position to confirm other descriptions of her or his experience. The pervasiveness of the notion of ownership of experience accounts here for the persuasive force of circular questioning. When, for instance, a client's partner describes what he or she sees as the client's 'greatest concerns regarding the test results,' it is up to the client, as the owner of the experience, to confirm or disconfirm those views. The conversational phenomenon at work here was first identified by Anita Pomerantz (1980, see also Bergmann, 1992) and termed by her as 'telling my side' as a device for 'fishing' for information. Describing our view on issues that we have only limited access to is a way to invite the one with authoritative access to disclose his or her version. Peräkylä's work shows how this device takes on a double force, used by the counselor in a circular interview setting.

Peräkylä (1995; see also Buttny, 1996) also described strategies that counselors use to engage the clients in talk about 'dreaded' issues (death, dying, or loss), among them the use of hypothetical questions that are ideally positioned after a dreaded scenario has already been hinted at in the conversation.

The focus on the client's perspective also affects issues of advice giving in HIV counseling, and it does so from two different angles. First, in certain counseling settings it may be viewed as important to give advice without implying its direct relevance to the

recipient. Such a case is HIV pretest counseling, where advice may be designed as neutral, general information (Silverman, 1997) – information that 'we give everyone in this institution.' This constitutes a way of delivering information about HIV and AIDS without having to ask the client to disclose personal information on delicate issues such as sexual behavior and without the implication that the recipient of advice is HIV positive.

Second, at issue is how advice, based on expert knowledge, can be designed so that it would be aligned with the advisee's perspective. Advice giving has been a central focus in studies of counseling interaction (Kinnell and Maynard, 1996; Silverman, 1997; Vehviläinen, 2001). Advice is a central task of the counselors, while it involves the problematics discussed above. Advice contains a normative dimension and a recommendation toward a course of action that the advice giver prefers, and it is given with the expectation that the recipient will treat it as relevant, helpful, or newsworthy and accept it. Advice giving implies that the adviser has knowledge or insight that the advisee lacks. Thus, it positions the participants asymmetrically. Therefore, advice giving is, inherently, a potentially problematic activity.

Within health care and counseling, research has identified sequences where the professional elicits the client's perspective prior to giving the expert view. This is done so as to fit and align the professional's perspective with that of the client and to minimize resistance. For instance, Maynard (1991) identified a 'perspective display series' in which doctors ask for the recipient's view prior to delivering diagnostic news to parents of children who have been diagnosed as having developmental difficulties (*see also* **Medical Discourse: Doctor–Patient Communication**). Heritage and Sefi (1992) found that when advising mothers of infants during home visits, British health visitors used questions to approach and develop a potentially problematic issue prior to giving advice regarding the problem.

Such 'stepwise' entry to advice has been identified in many counseling settings as well, and it has been shown to facilitate the uptake of advice, minimize resistance, and enable the counselor to design advice so as to take into account the client's perspective (Silverman, 1997; Kinnell and Maynard, 1996); it has also been shown to legitimize advice in a setting where directive advice is not considered appropriate and to give the counselor's advice argumentative strength that has pedagogical relevancy in an educational counseling setting (Vehviläinen, 2001; *see also* **Classroom Talk**).

This practice of advice giving deals with, on the one hand, the dilemma of simultaneous orientation to the importance of the client's own perspective and experience and, on the other hand, maintenance of the authority of the professional's perspective. This issue is particularly prominent in counseling. Counseling practices entail an inherent contradiction: clients should be 'empowered' and their self-directedness increased. At the same time, counseling often has other aims that contradict these ideals and put the professional in the position of an authority.

Although therapy and counseling are, ideologically, seen as modes of facilitating the client's own healing, introspecting, or problem-solving, many researchers of therapeutic interaction view it as an art of persuasion (Davis, 1986; Buttny, 1996). Indeed, many psychotherapies work from the basis of a notion of denial – the clients may not be conscious of, or willing to face, what are taken to be the true reasons of their problems. Thus, the professionals take upon themselves the task of bringing about a change in the way in which the clients see themselves or their problems.

Puerto Rico: Language Situation

R Cameron, University of Illinois at Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Speaking of language in Puerto Rico is different from speaking of the language situations of Puerto Ricans. Owing to consistent migration to and from the continental United States and owing to the island's control by the United States since 1898, the Puerto Rican community extends well beyond the Caribbean. The 2000 U.S. Census reports a total Puerto Rican population in the continental United States of 3 406 178. On the island, the population figure is 3 623 392. However, the island is not solely populated by individuals of Puerto Rican descent. This diversity contributes a measure of linguistic diversity to the island even as Puerto Rican island society is overwhelmingly and securely Spanish speaking. The census reports that 85% of the population on the island of Puerto Rico above the age of 5 speaks Spanish. Roughly 55% speak English to varying degrees. However, 14% of the population speaks only English and approximately 1% speaks other languages as well. Apart from Puerto Rican Spanish, four other countries contribute significant numbers: the Dominican Republic, Cuba, Mexico, and Spain. Smaller groups come from Colombia, Venezuela, and Panama. One may also find social networks in which Haitian Creole, Chinese, Arabic, Japanese, and French are spoken. Many of these speakers also speak a dialect of Spanish or English as a second language. Nonetheless, this diversity is not represented in either the media or education where Spanish and English predominate. Public schooling is in Spanish, with English taught as a second language.

Puerto Rico: Language Situation

R Cameron, University of Illinois at Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Speaking of language in Puerto Rico is different from speaking of the language situations of Puerto Ricans. Owing to consistent migration to and from the continental United States and owing to the island's control by the United States since 1898, the Puerto Rican community extends well beyond the Caribbean. The 2000 U.S. Census reports a total Puerto Rican population in the continental United States of 3 406 178. On the island, the population figure is 3 623 392. However, the island is not solely populated by individuals of Puerto Rican descent. This diversity contributes a measure of linguistic diversity to the island even as Puerto Rican island society is overwhelmingly and securely Spanish speaking. The census reports that 85% of the population on the island of Puerto Rico above the age of 5 speaks Spanish. Roughly 55% speak English to varying degrees. However, 14% of the population speaks only English and approximately 1% speaks other languages as well. Apart from Puerto Rican Spanish, four other countries contribute significant numbers: the Dominican Republic, Cuba, Mexico, and Spain. Smaller groups come from Colombia, Venezuela, and Panama. One may also find social networks in which Haitian Creole, Chinese, Arabic, Japanese, and French are spoken. Many of these speakers also speak a dialect of Spanish or English as a second language. Nonetheless, this diversity is not represented in either the media or education where Spanish and English predominate. Public schooling is in Spanish, with English taught as a second language.

Private schooling provides a wider range of language options. Owing to the lengthy colonial relationship with the United States, debate about the future of Spanish and English is highly charged. Any discussion of language policy, teaching, or planning entails issues of Puerto Rican identity, either personal or political.

Puerto Rican Spanish, as in other Spanish-speaking Caribbean countries, historically derives from the Andalusian and Canary Island regions of Spain. Prior to the arrival of the Spanish, the indigenous peoples spoke Taíno, a variety of Arawak. However, the Taíno people died within 50 years of European settlement. They left behind multiple place names (Mayagüez, Humacao) and other vocabulary for plants, animals, musical instruments, weather events, or household objects and spaces: *maní* 'peanut', *guaraguao* 'hawk', *güiro* 'percussion instrument', *huracán* 'hurricane', *hamaca* 'hammock', *batey* 'patio'. English has also provided a sizable number of borrowings, many of which are found in other dialects as well. Consider *closet*, *béisbol*, *sandwich*, and *family room*. There is some regional variation on the island, with a major division occurring between the west and the east. This variation includes vocabulary, some features of pronunciation, and, perhaps, an important quantitative difference, though more research is needed. Being a null subject language, Spanish provides speakers with the option of expressing subjects as pronouns, lexical noun phrases, or null subjects as in *yo camino* 'I walk' or *camino* '__ walk'. Generally, Puerto Rican Spanish shows a relatively high frequency of subject pronoun expression. Moreover, (non)-specificity of reference for second person subjects correlates with differing frequencies of pronominal expression. Yet speakers from the central region around Lares appear to have a distinctly lower frequency of pronominal expression, similar to dialects from Spain. This differs from findings for the major city of San Juan. Other quantitative sociolinguistic research finds evidence of age, gender, class, network, and stylistic patterning for phonological variables such as aspiration/deletion of syllable-final /s/, spirantization/deletion of intervocalic /d/, velarization of syllable final /n/, neutralization of syllable final /l/ and /r/, assibilation of /rr/, a weakening of /č/ toward /š/, spirantization of /y/, and variable raising of unstressed word final /e/ and /o/.

Two syntactic variables also show social and stylistic patterning. One involves the variable fronting of subject pronouns in wh-questions as in *¿Qué tú dijiste?* 'What did you say?' The other involves alternation between three strategies for expressing a direct quotation. Research on both syntactic variables suggests change in progress.

One final note: contrary to many public expressions of concern that English has influenced or corrupted Puerto Rican Spanish, no sociolinguistic research has clearly documented any English-induced changes in the phonology or syntax of the language.

Punctuated Equilibrium and Language Change

C Bowern, Rice University, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

The theory of 'punctuated equilibrium' was originally developed by Nils Eldredge and Stephen J. Gould as an alternative to gradual Darwinian evolution in biology. In their model, evolutionary change occurs rapidly among small, peripheral populations, which may later spread out over a larger geographical area, obliterating other populations and creating what appear to be breaks in the fossil record. The alternative, 'phyletic gradualism,' assumes that species mutate gradually over large interconnected populations. Punctuated equilibrium is controversial in evolutionary biology and has met with differing levels of acceptance in the literature.

Many researchers have adapted punctuated equilibrium to their own fields. In linguistics, it seems to have been first taken up first by Thurston (1987) and later by Heath (1998). Thurston is particularly concerned with notions of gradual versus abrupt change. Heath argues that equilibrium is defined by isolated monolingualism, while periods of punctuation involve intense contact. The most commonly quoted application of punctuated equilibrium, however, is in several works of R. M. W. Dixon, most notably in *The rise and fall of languages*. His view differs from both Thurston's and Heath's. Dixon's formulation will be considered from here on. In developing his model Dixon sought to explain several pieces of data and to correlate types of linguistic change with different types of sociocultural events.

Under Dixon's model, language change (and history in general) is assumed to be characterized by long periods of stasis (or 'equilibrium') and much shorter periods of 'punctuation'. Language groups are assumed to have coexisted for most of human

Punctuated Equilibrium and Language Change

C Bowern, Rice University, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

The theory of 'punctuated equilibrium' was originally developed by Nils Eldredge and Stephen J. Gould as an alternative to gradual Darwinian evolution in biology. In their model, evolutionary change occurs rapidly among small, peripheral populations, which may later spread out over a larger geographical area, obliterating other populations and creating what appear to be breaks in the fossil record. The alternative, 'phyletic gradualism,' assumes that species mutate gradually over large interconnected populations. Punctuated equilibrium is controversial in evolutionary biology and has met with differing levels of acceptance in the literature.

Many researchers have adapted punctuated equilibrium to their own fields. In linguistics, it seems to have been first taken up first by Thurston (1987) and later by Heath (1998). Thurston is particularly concerned with notions of gradual versus abrupt change. Heath argues that equilibrium is defined by isolated monolingualism, while periods of punctuation involve intense contact. The most commonly quoted application of punctuated equilibrium, however, is in several works of R. M. W. Dixon, most notably in *The rise and fall of languages*. His view differs from both Thurston's and Heath's. Dixon's formulation will be considered from here on. In developing his model Dixon sought to explain several pieces of data and to correlate types of linguistic change with different types of sociocultural events.

Under Dixon's model, language change (and history in general) is assumed to be characterized by long periods of stasis (or 'equilibrium') and much shorter periods of 'punctuation'. Language groups are assumed to have coexisted for most of human

history without a great deal of social or natural disruption. During such periods of 'equilibrium,' languages slowly change, largely by borrowing from one another. In this way traits can diffuse across an area. Thus, during these equilibria, local as well as larger linguistic areas are created, cross-cutting boundaries of 'genetic' families. As a consequence, languages that are not genetically related (i.e., though the inheritance of linguistic material forms a common ancestor) may nonetheless come to share considerable material.

The long periods of equilibrium are interspersed with much shorter periods of 'punctuation.' Punctuation could be caused by several factors, either natural or manmade. The introduction of new technology, invasion, mass migration, fire, or flood are some examples of punctuation. It is only in times of punctuation that recognizable language splits occur, of the kind well modeled by a family tree and of the type usually thought of as indicative of genetic relationships.

According to Dixon, equilibrium has been the natural state for most of the world's languages for most of human history, while the family tree model is applicable only in the time following a punctuation and language spread. Thus (in Dixon's model) languages change at different rates at different times, but the rate is loosely tied to whether the language is in a state of punctuation or equilibrium. Languages in equilibrium will "converge to a common prototype"(Dixon, 1997: 71); that is, they will tend to continue borrowing lexical items and grammatical structures until they reach approximately 50% in common (first proposed in Dixon, 1970; see Dixon, 1972 for a more accessible formulation). According to Dixon, any lexical or grammatical component of a language can be borrowed, although languages tend to borrow vocabulary more easily than grammatical items. However, he states that there is no universal that basic vocabulary is borrowed less than nonbasic vocabulary. Therefore, adjacent languages that have little in common are likely to have come into contact relatively recently.

The model is based on some empirical observations and some negative evidence. Firstly, if languages had diverged at the rate of the Indo-European or Austronesian families over the last 100 000 years, we would expect to find many more languages than the 6500 or so that are spoken today (more than 10^{34}, Dixon calculates). That rate of change cannot be constant across all language families at all times. Secondly, the 'standard model', or the 'family tree model,' seems to approximate the linguistic situation much better in some parts of the world than in others. Dixon frequently uses Indo-European and Austronesian as examples of families where the method succeeds, and Australia as a paradigm case of where the method fails. Finally, punctuated equilibrium provides a way to link together nonlinguistic events and their reflections in the linguistic record, thereby 'explaining' why some areas of the world have proven difficult to model using the family tree.

Fundamental for punctuated equilibrium is that the family tree model of linguistic relationship is only applicable in a period following a punctuation; at other times, Dixon argues, there has been so much diffusion between adjacent languages that borrowing clouds any recognizable splits. He argues that this is the case in some parts of the world, particularly Australia, where linguistic relationships are difficult to model on a family tree. Thus, he draws the inference that macro-families such as 'Nostratic' are misguided for rather different reasons from what is normally supposed; while most people reject reconstructions of 'Nostratic' because of the paucity of recurrent correspondence sets and the difficulty and uncertainty of comparing proto-languages (see, for example, Campbell, 1998), Dixon primarily rejects it because beyond the recent spread and split of Indo-European languages, the family tree model is not applicable.

Punctuated equilibrium has been enthusiastically endorsed in some quarters because it provides a way of tying hypotheses about language relationships to technological innovations. Work by Colin Renfrew and Peter Bellwood has been prominent in this regard. For example, they link the spread of the Indo-European language family to the spread of agriculture (arguing for the spread of agricultural technology as a major punctuation). Bellwood uses similar arguments for the spread of the Austronesian family in Asia.

Despite the enthusiasm for punctuated equilibrium among some prehistorians, historical linguists have been quite critical of the model, and support for punctuated equilibrium as an explanatory model of linguistic prehistory seems largely confined to archaeologists. Criticisms have been focused on the underlying assumptions of the model (for example, that linguistic and nonlinguistic events can be directly correlated), the data adduced as evidence, and the model's application to particular families and parts of the world.

Let us first consider criticisms of the architecture of the model. Dixon does not overtly distinguish in the model between the languages of the 'punctuators' and those of the 'punctuatees' (that is, speakers of languages who cause a punctuating event versus those who suffer one). Both the punctuator and the punctuatee speakers/languages are undergoing punctuation, but with different effects. 'Punctuator'

languages, for example, can show substratum influences (see, for example, the development of a set of retroflex consonants in Indic languages); thus, language contact and convergence is not the province of equilibrium situations alone. Many cases of convergence are actually the result of (in Dixon's terms) short-term punctuation, and not long-term equilibrium.

Secondly, not all punctuations result in family-tree-like splits. Turkic languages, for example, would seem to be a good example of a family undergoing 'punctuation'. Yet the internal relationships between Turkic languages are very complicated and are the subject of ongoing dispute (see, for example, the discussions by Schönig, 1997 or Tekin and Ölmez, 1995). The Indo-European family itself is not nearly as clear-cut as Dixon argues, as seen by debate on the status of higher-order subgroups such as Italo-Celtic, Greek-Indo-Iranian and the date of the splitting off of Germanic.

Others have argued that punctuated equilibrium oversimplifies language contact. Watkins, for example, provides illustration of cases from Anatolia where 'regular' family-tree-like changes and language contact are going on at the same time. He sees no reason for separating areal developments and genetic developments, because the two occur concurrently. Dixon's notion of equilibrium assumes symmetrical borrowing patterns as the norm (that is, the convergence of two languages by mutual borrowing); it is known from many studies in the literature that accommodation need not be symmetrical (see, for example, Heine and Kuteva, 2001 and Thomason and Kaufman, 1988).

Just as Eldredge and Gould's punctuated equilibrium was an alternative to a received theory, so too Dixon aimed to provide an alternative to a set of standard assumptions, in this case, the comparative method and the family tree model. Although Dixon challenges the applicability of the family tree model to certain language families, he does not challenge the principle of the regularity of sound change or the applicability of the comparative method in broad terms. Dixon's arguments against the comparative method and the relative advantage of punctuated equilibrium are misplaced. The comparative method is based on the assumption that internal language change is regular, and that regular, systematic correspondences between languages are meaningful and highly unlikely to be due to chance. Furthermore, sound change is usually highly regular, and exceptions require further investigation (such as loanword analysis, dialect interference, back-borrowing). Nor does the comparative method necessarily lead to the drawing of a family tree for the languages under analysis. The comparative method can still be used, for example, within linguistic areas and in the analysis of loanwords. For an Australian example, see work by Harold Koch on loanwords between Arandic languages and Warlpiri.

Dixon further criticizes the comparative method because it will overgenerate in some cases. For example, if a change occurs in all the languages of a group independently, the change may well be reconstructed to the ancestor of the group, giving the false appearance of a common innovation (in the absence of evidence from relative chronology). We cannot reconstruct states for which we have no evidence. This is, of course, a weakness of the comparative method; however, it is a problem with all reconstructions of the past – if evidence has been obliterated, we cannot see it, no matter what the method used, be it carbon-dating, stratigraphy, thermo-luminescence, punctuated equilibrium, or glottochronology. This is not a valid criticism of the comparative method *per se*, it is a fact of making hypotheses about prehistory.

Finally, some comments are warranted on the application of punctuated equilibrium to Australia, as it is one of the few areas of the world where the model is claimed to have empirical support. Punctuated equilibrium has found little support among historical linguists working on Australian languages, as there is a considerable amount of evidence contradicting Dixon's model (see, for example, the papers in Bowern and Koch, 2004).

Dixon assumes that Australian languages have been evolving largely *in situ* from a period shortly after the initial settlement of the Australian land mass, probably around 60 000 years ago. His reasons are partly to do with origin myths (cf. Dixon, 1996) and partly because, as he states, if Proto-Australian had been spoken only a few thousand years ago, the split and expansion would have happened rather recently, and a family tree model should be applicable. One set of languages, called the Pama-Nyungan family, is taken to be an archaic diffusion area, with few genetic groups. In contrast, most other Australianists prefer a model under which speakers of Pama-Nyungan languages spread out across most of Australia, their movement perhaps governed by climatic change at the end of the Pleistocene (that is, more than 50 000 years later than Dixon's claim). Under this view, we can infer nothing about initial dispersal from the current distribution of languages. There is considerable archeological evidence for site abandonment and resettlement in various parts of the continent, for continual 'punctuations' (in Dixon's terms) caused by climatic variation, and for population movement.

Linguistics and biology have long borrowed metaphors, terminology, and ideas back and forth.

Punctuated equilibrium has proved appealing to those who wish to link types of linguistic change to events in prehistory; however, correlations in events and linguistic outcomes are elusive. Several areas in the world would appear to be counterexamples to the principles of punctuated equilibrium and the flagship case, Australia, is perhaps not as immune to reconstruction by traditional methods as Dixon has suggested. It remains to be seen how durable a framework punctuated equilibrium can be for linguistic prehistory.

Punctuation

J Lawler, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

'Punctuation' refers to various systems of dots (Latin *punctus*) and other marks that accompany letters and other glyphs as part of a writing system. Although there is a certain overlap among the various kinds of marking, punctuation proper should be distinguished from diacritic marks, which are intended as modifications of individual letters (e.g., *ö ő å í è ç š ū ñ ŋ̊*) and are often simply considered to be part of the letter they appear on, like the dot on the Latin lower case *i* or the ear on Vietnamese *ơ ư*, as well as from logographs, which are simply one-glyph representations of lexical items (e.g., @ # $ % &). Several other common glyphs, such as the slash, indicating alternation (*and/or*), or the asterisk *, indicating some special qualification like a footnote or ungrammaticality, are intermediate between these categories, but are not considered true punctuation. This article will consider only punctuation marks that appear separately from other written glyphs and have no lexical reference.

The modern suite of punctuation marks includes the period ⟨.⟩, comma ⟨,⟩, colon ⟨:⟩, semicolon ⟨;⟩, left and right parentheses ⟨( )⟩ (and other brackets, square ⟨[ ]⟩ and curly ⟨{ }⟩), interrogation and exclamation marks ⟨? !⟩ (bracketed with their inverses ⟨¿ ¡⟩ in Spanish), dashes of several lengths ⟨- – —⟩, single and double quotation marks ⟨'"« »"'⟩, and the apostrophe or raised comma ⟨'⟩ (not to be confused with the prime mark ⟨′⟩, which is a diacritic).

This suite, with minor variations, is in use today in practically all alphabetic writing systems in the world, and many nonalphabetic ones, with a set of uses that is remarkably similar across languages. In this regard, punctuation may be considered a supralinguistic representational system, like Arabic numerals. Unlike Arabic numerals, however, punctuation is of recent adoption (Shakespeare's punctuation, for instance, is quite different from that of Modern English); it is subject to great individual variation (like handwriting, or spelling before the introduction of printing); and there is no consensus as to how it should be used (though there is no shortage of prescriptivist fulmination, all incomplete and contradictory in one way or another; e.g., Truss, 2004). Thus, it must also be considered a representational system that is still in the process of being standardized, and may not in fact ever achieve standardization.

Punctuation has several uses, one of which is to mark the boundaries of certain structural constituents of written language, identifying them as units and separating them from other textual units. The simplest example of this is the space that appears between words in English and most other alphabetic writing systems. This is a fairly recent innovation in writing: classical Latin and Greek writing, for instance, did not leave spaces between words, and modern Thai still does not. Another example is the use of a period to mark the end of a grammatical sentence. (The convention of starting the first word of a sentence with a capital letter may be considered part of punctuation, spelling, diacritic marking, or even grammar, depending on how one defines each term; in any event, letter case distinctions are also of recent origin in European writing, dating, like spelling standardization, from the widespread establishment of printing.)

Another use of punctuation is to indicate textual relations between higher-level constituents such as phrases and clauses that are not obvious from the syntax. An example of this kind of usage is the semicolon in English. The semicolon is a full stop in terms both of intonation (it is aurally indistinguishable from a period) and grammar (it follows a complete sentence). But, as Thomas (1979) put it, "The semicolon tells you that there is still some question about the preceding full sentence; something needs to be added." Another example is the colon, which must be followed by some unit that constitutes an 'extension' of the constituent preceding the colon: a list of examples, a clause defining it, or simply its name.

Still another use – indeed, the original use – of punctuation is to provide some indication of the intonational and rhythmic intentions of the writer, as the written words indicate the lexical and grammatical intentions. For instance, the comma in English is often claimed to represent an intonation sequence of *mid-low-high-mid*, like the one used in counting: *fifty-one, fifty-two, fifty-three, fifty-four* ⋯. Punctuation serves, to those who follow this theory, to represent the 'authorial voice,' and guide conventions for reading aloud. This applies to English only, and should not be considered to apply to other languages, such as German, where the rules for punctuation are specifically governed by syntactic considerations.

Since much if not most reading (and writing) takes place without any aural stimulus at all, there is considerable doubt as to the empirical (not to speak of the epistemological) nature of this representation. The most authoritative modern studies (Nunberg, 1990; Nunberg *et al.*, 2001) have taken the position that "it is not clear what explanatory purpose would be served by saying that punctuation 'transcribes' [such inner voices], particularly when, as with colons

or parentheses, they have no actual correlates in ordinary speech" (Nunberg, 1990: 15).

However, the vast individual differences in punctuation of English suggest that writers use a multitude of contradictory rules in their punctuation; and that there is no reason to expect this situation to change soon.

Introduction

Punjabi is a modern Indo-Aryan language spoken in primarily two South Asian countries: India and Pakistan and also in countries outside South Asia (the United Kingdom, Canada, Malaysia, Indonesia, Singapore, Fiji, United Arab Emirates, Kenya, South Africa, and other countries). The name Punjabi (also spelled Panjabi) is derived from Punjab, the land of five rivers (the Jehlam, the Ravi, the Chanab, the Vyas, and the Satluj).

Approximately 50 million people speak Punjabi as either a first or second language. It is the official language of the state of Punjab in India. Although the official language of Pakistan is Urdu, it is spoken as a native language by just 8% of the population; the majority native language is Punjabi, spoken by approximately 60% of the population. Punjabi is ranked among the top 20 most widely spoken languages in the world.

With the partition of the Indian subcontinent came the partition of the State of Punjab. So massive was the migration in 1947 that it is viewed as the greatest migration in the history of humanity. About 10 million people were uprooted from both sides of what is now India and Pakistan. Consequently, the population of the Punjabi-speaking area underwent radical reorganization, which had and continues to have an impact on the language in term of norms, multiple identities, and language standardization.

History and Literature

Punjabi, which is a descendant of the Sanskrit language, belongs to the Indo-Aryan language family. It has been in use as a literary language since the 11th century. Punjabi has three distinct historical stages: Old (10th–16th centuries), Medieval (16th–19th centuries), and Modern (19th-century to the present). The most important treatise of the Old Punjabi is *A:di grantha*, the sacred scripture of the Sikhs.

Varieties and Dialects

In addition to the national varieties, Punjabi has several regional, religious (Hindu, Sikh, and Muslim), and socioethnic varieties. The four regional varieties of Eastern Punjabi are as follows:

1. Majhi, the standard variety, is spoken in the districts of Amritsar and Gurdaspur.
2. Malwi is found in the districts of Bhatinda, Ferozpur, Ludhiana, the western parts of Patiala and Sangrur.

or parentheses, they have no actual correlates in ordinary speech" (Nunberg, 1990: 15).

However, the vast individual differences in punctuation of English suggest that writers use a multitude of contradictory rules in their punctuation; and that there is no reason to expect this situation to change soon.

Introduction

Punjabi is a modern Indo-Aryan language spoken in primarily two South Asian countries: India and Pakistan and also in countries outside South Asia (the United Kingdom, Canada, Malaysia, Indonesia, Singapore, Fiji, United Arab Emirates, Kenya, South Africa, and other countries). The name Punjabi (also spelled Panjabi) is derived from Punjab, the land of five rivers (the Jehlam, the Ravi, the Chanab, the Vyas, and the Satluj).

Approximately 50 million people speak Punjabi as either a first or second language. It is the official language of the state of Punjab in India. Although the official language of Pakistan is Urdu, it is spoken as a native language by just 8% of the population; the majority native language is Punjabi, spoken by approximately 60% of the population. Punjabi is ranked among the top 20 most widely spoken languages in the world.

With the partition of the Indian subcontinent came the partition of the State of Punjab. So massive was the migration in 1947 that it is viewed as the greatest migration in the history of humanity. About 10 million people were uprooted from both sides of what is now India and Pakistan. Consequently, the population of the Punjabi-speaking area underwent radical reorganization, which had and continues to have an impact on the language in term of norms, multiple identities, and language standardization.

History and Literature

Punjabi, which is a descendant of the Sanskrit language, belongs to the Indo-Aryan language family. It has been in use as a literary language since the 11th century. Punjabi has three distinct historical stages: Old (10th–16th centuries), Medieval (16th–19th centuries), and Modern (19th-century to the present). The most important treatise of the Old Punjabi is *A:di grantha*, the sacred scripture of the Sikhs.

Varieties and Dialects

In addition to the national varieties, Punjabi has several regional, religious (Hindu, Sikh, and Muslim), and socioethnic varieties. The four regional varieties of Eastern Punjabi are as follows:

1. Majhi, the standard variety, is spoken in the districts of Amritsar and Gurdaspur.
2. Malwi is found in the districts of Bhatinda, Ferozpur, Ludhiana, the western parts of Patiala and Sangrur.

3. Doabi is spoken in the districts of Jallandar, Kapurthala, and Hoshiarpur.
4. Powadi is dominant in the district of Ropar, and the eastern parts of Patiala and Sangrur.

There are four additional traditionally recognized dialects of Punjabi (Rathi, Ludhianwi, Patialwi, and Bhattani), whose status as independent dialects is subject to dispute. Lahanda (also called Saraiki and Multani), which is classified as Western Punjabi by Grierson (1916), is questioned by language authorities. The Saraiki, Hindoko, and Pothohari (also called Patohari, Pothwari, Putohari, Pothohari, Mirpuri Punjabi) language movements in Pakistan assert the three varieties as three separate languages in their own right rather than as three dialects of Punjabi (see Rahman, 1996 for details).

Writing Systems

Punjabi is written primarily in three scripts: Gurmukhi, Perso-Arabic, and Devanagari. Sikhs often write Punjabi in Gurmukhi, Hindus in Devanagari, and Muslims in Perso-Arabic, called Shahmukhi. Punjabi written in Gurmukhi is the official language/script of the Indian state of Punjab. In addition to these three scripts, Punjabi is also recognized for its business scripts, such as LaNDa, Mahajani, and Baniyakar. These scripts, although now dying, are particularly noteworthy not only for their telegraphic and 'shorthand' characteristics employed in clerical and business domains, but also as a secret code.

Phonology

Punjabi has four notable phonological features.

First, Punjabi is the only modern Indo-Aryan language that has developed tonal contrasts.

- The low tone / `/ is characterized as low-rising tone.
- The high tone / ´/ is characterized as a rising-falling tone.
- The mid tone / -/ is never represented by the accent mark since it is predicted by rules of redundancy.

The following examples reflect the phonemic status of the level tones:

/kàR/ 'chisel'
/kaR/ 'bottom'
/káR/ 'boil.'

Although tones are phonemic, none of the three scripts (Gurmukhi, Devanagari, and Perso-Arabic [Shahmukhi]) have any symbol or accent mark to identify tones; instead voiced aspirated consonant symbols are used, which reflect either the older (Eastern) Punjabi or modern Western Punjabi pronunciation. Thus, there is a close correlation of voiced aspirates (e.g., of languages such as Hindi) and the Punjabi tones.

Second, Western Punjabi still retains the original Indo-European (1500 B.C.) distinction between aspirated and unaspirated consonants, which results in a four-way contrast, as shown in the following examples:

ka:l 'time'
kha:l 'skin'
ga:l 'cheek'
gha:l 'to put into'

In Eastern/Standard Punjabi, this four-way contrast is reduced to a three-way contrast: unvoiced unaspirate, unvoiced aspirate, and voiced unaspirate. The voiced aspirates yield tones.

Third, it has the feature of retroflexion in its consonant inventory,

Ta:l 'to put off'
ta:l 'pond'

The retroflex consonant is transcribed as the capital T. In addition to the retroflex stop, Punjabi has a fricative, flaps, and a lateral.

Fourth, geminates are another distinctive feature of Punjabi. All consonants except N, L, R, y, h, and w may be geminate (doubled). Gemination is represented by the *addak/adhak* sign in Gurmukhi.

The inventory of distinctive segments of standard Punjabi is as follows. The symbol (·e) indicates the sounds that occur in Perso-Arabic words (Table 1).

Glottal h appears only in the word-initial position.

Punjabi vowels may be oral or nasal. The distinction is phonemic: *ga:* 'sing' and *gã:* 'cow' (Table 2).

Stress

Although stress (meaning loudness) is not a prominent feature of Punjabi, it seems that its existence cannot be denied. Stress can distinguish between grammatical categories such as nouns and verbs, as in:

Nouns	Verbs
galaa 'neck'	ga**laa** 'cause to melt'
talaa 'sole'	ta**laa** 'cause to fry'

The stressed syllable is shown in bold. However, stress is not usually distinctive in Punjabi. Therefore, in general, whether one places stress on the first syllable or on the second, the meaning will not be affected. For example, the meaning of the word *suNa:* 'heard' will remain unchanged whether one places stress on the first syllable or the second. Therefore, Punjabi is

Table 1 Consonants

		Labial	*Dental*	*Retroflex*	*Palatal*	*Velar*	*Back velar*

	i		u
Mid	e		o
	ai	a [schwa]	au
Low		a:	

often characterized as a syllable-timed language like French, where the syllables are pronounced in a steady flow, resulting in a 'machine-gun' effect.

Morphology

Word formation in Punjabi primarily uses prefixes and suffixes to define inflectional and derivational word classes. Nouns are generally inflected for number, gender, and case. There are two numbers, singular and plural; two genders, masculine and feminine; and three cases, simple, oblique, and vocative. The oblique forms occur when a noun or a noun phrase is followed by a postposition. Nouns are inflected according to their gender and word-final sound, as exemplified by the three paradigms given in Table 3.

Adjectives are primarily of three types:

1. Simple adjective, such as *canga:* 'good';
2. Derived adjectives employing various parts of speech such as nouns: *marda:na:* (from *mard* 'man') 'masculine,' adverbs: *manda:* 'slow' (from *mand* 'low'), and from agentive/adjectival particle *va:la:* e.g., *dilli: va:la:* (from *dilli:* 'Delhi' *va:la:* '-er') 'from Delhi';
3. Participial adjectives: *caldi:* 'moving,' *nasda:* 'running.'

Adjectives can be used both attributively (immediately placed before nouns) and predicatively (immediately placed before verbs). Simple, Participial, and *va:la:* adjectives are of two types, inflected and uninflected. Inflected adjectives agree with their following noun in number, gender, and case; they end in morpheme *-a:* (e.g., *canga:* 'good'), which changes to *e* for masculine plural and masculine oblique (*cange*), *-ii* for feminine singular (*cangi:*) and *-iã:* for feminine plural nouns (*cangiã:*). Uninflected adjectives (not ending in *-a:*) remain unchanged.

Although the case system of pronouns is essentially the same as that of nouns, pronouns have more case forms than nouns. Case relations are essentially carried out by means of postpositions. Personal pronouns are similar to their English equivalents; however, there are no gender distinctions (like *he* and *she* in English) (Table 4).

Adverbs and postpositions are invariant, except for the genitive postposition, which behaves like an inflected adjective. The postpositions mark case relations and adverbial functions.

Verbs

There are three tenses in Punjabi: present, past, and future. The tenses are formed by the suffixation process. Verbs are inflected for number, gender, and person.

ó a:-nd-a: ai.
he come-PRES-MASC. Sing is
'He comes.'

ó aa-iyaa.
he come-PERF.MASC.Sing.
'He came.'

ó aa-e-g-aa
he come–3Sing-FUT-MASC. Sing
'He will come.'

In addition to simple verbs, Punjabi has two categories termed 'conjunct' and 'complex' verbs. The class of conjunct verbs is usually derived adding *karnaa* 'to do' or *hoNaa* 'to be' to noun, adjective, pronoun, or adverb, for example:

Table 3 Punjabi noun paradigms

Case	*Paradigm I: masculine nouns ending in* −a: *(e.g.,* muNDa: *'boy')*		*Paradigm II: masculine nouns not ending in* −a: *(e.g.,* a:dmi: *'man')*		*Case*	*Paradigm III: all feminine nouns (e.g.,* kuRi: *'girl')*

Direct	mãi	asĩ:	tu:	tussi:	ó	ó
Oblique	mã	sa:	tãi	tvà:	ó	ónha:
Genitive	mera:	sa:Da:	tera:	tuvà:Da:	óda:	ónha:da:

kamm 'work,' kamm karNa: 'to work'

canga: 'good,' canga: hoNa: 'to recover'

tez 'fast,' tez karNa: 'to speed up'

Complex verb: likh 'write', laiNa: 'to take'-→ likh laiNa: 'to write' (for one's own benefit)'

Punjabi is also sensitive to stative/active and volitional/nonvolitional distinction; these four types of distinction are denoted by morphologically related verbs:

khulNa: 'to be opened,' kholNa: 'to open'

TuTNa: 'to be broken,' toRna: 'to break'

Causative verbs are derived by adding *-a:-*, for the simple causative, and *-wa:-*for the double causative, to the stem of the verb.

Compounding is an integral and very productive process of word formation in Punjabi. The noun-noun compounding involves twelve types of compounding. For example, *kha:Na:* 'eating' and *pi:Na:* 'drinking' can be compounded into *kha:N-pa:N* 'life style.'

From the viewpoint of morphological complexity, Punjabi can be classified as an agglutinating language. Derivation of words takes place by the addition of suffixes to simple or derived stems of major word classes. The process of prefixation is almost exclusively used with nouns and verbs, other word classes rarely participate in this process. The process of suffixation is equally productive with both nouns and verbs.

Syntax

Punjabi is a Subject Object Verb (SOV) language with relatively fixed word order. Interrogative or other sentence types do not introduce any changes in word order. In topicalization and focus structure, however, phrases occurred in marked position, usually initial. It is primarily a head-final language. The verb generally agrees with the subject. In transitive perfective sentences, the third person subject is marked with the *ne* postposition, and the verb agrees with the direct object. As a rule of thumb, the verb never agrees with any constituent, which is marked with a postposition.

Any sentence can be negativized by placing the negative particle *nahii* 'not' in the preverbal position. Punjabi is a Pro-drop language. In the following sentence, the subject can be dropped.

nahĩ: a:-e-g-a:
not *come–3Sing-FUT-MASC. Sing*
'(he) will not come.'

Language Contact

Punjabi borrows from Sanskrit, Persian, Arabic, Hindi-Urdu, and recently, English.

Punning

K Sornig, University of Graz, Graz, Austria

© 2006 Elsevier Ltd. All rights reserved.

The irresistible urge of humans to play metacommunicatively upon any means of communication (especially language) has given rise to the near-universal pastime of punning. From another point of view, puns can be said to originate in the fact that humans (despite many philosophers' assertions to the contrary) cannot (or even will not) always speak unequivocally. Puns are a kind of playful handling of lexical items whose similarities in surface structure are contrasted with differences in deep, semantic structure. The principle of similarity/affinity that is at work here is equally important in rhymes and alliteration, spoonerisms, and folk etymology, as well as in irony and metaphors: "every metaphor contains a pun" (Huizinga, 1956: 12) (*see* **Irony**; **Metaphor: Psychological Aspects**).

The phonemic constellations that allow us to produce puns, both on the auditory level and (chiefly in languages that allow for orthographic irregularity, such as English) on the level of writing, are intrinsically language specific and therefore almost never accessible to translation. Punning is the skilled and creative native speakers' privilege and hallmark and consequently none of the foreigner's business.

Homophonous similarity functions with or without graphemic variation. The following are some examples:

(1) "How is bread made?" – "I know that", Alice cried eagerly, "you take some flour . . ." "Where do you pick the flower?" the White Queen asked . . . – "Well, it isn't picked at all", Alice explained: "it is ground . . ." – "How many acres of ground?" . . . (From Alice in wonderland; flour : flower)

(2) "if so 'tis the will of Whose B. Dun" (from Finnegan's wake, Joyce, 1975: 518).

In this case, the relative pronoun *whose* figures as part of a (homophonous, 'created') proper name (*Whose*).

Here is a psychological joke, in German, that was popular during World War II:

(3) First psychiatrist: "Heil Hitler!"
Second psychiatrist: "Heil du ihn!"
('Hail to Hitler!' – 'Heal him yourself!')

The joke stems from the fact that German *heil* can mean either 'hail' or 'heal'. In this example, moreover, we see how punning may transcend the boundaries of word categories, here noun versus verb.

A Turkish-based pun:

(4) 'Do you know the name of Michael Jackson's brother?'
'It's sikeceksin [djeksin]'

Here, Turkish *sik-* 'fuck' + suffix *–ecek* 'future' + pronominal ending 2.SING *-in* 'you' would be translated as 'you are going to fuck'. Thus, the proper name (*Jackson*) is played off against the grammatical suffixes *-(e)cek-sin*).

Finally, a Russian example:

(5) СПАСИТЕ НАШИ ШУТИ/АУШИ
spasite naši šuti/duši
'save our paunches/souls'

Here, the pun plays on the phonetic similarity of the Russian words for 'paunches' and 'souls'.

The irresistible urge of humans to play metacommunicatively upon any means of communication (especially language) has given rise to the near-universal pastime of punning. From another point of view, puns can be said to originate in the fact that humans (despite many philosophers' assertions to the contrary) cannot (or even will not) always speak unequivocally. Puns are a kind of playful handling of lexical items whose similarities in surface structure are contrasted with differences in deep, semantic structure. The principle of similarity/affinity that is at work here is equally important in rhymes and alliteration, spoonerisms, and folk etymology, as well as in irony and metaphors: "every metaphor contains a pun" (Huizinga, 1956: 12) (*see* **Irony**; **Metaphor: Psychological Aspects**).

The phonemic constellations that allow us to produce puns, both on the auditory level and (chiefly in languages that allow for orthographic irregularity, such as English) on the level of writing, are intrinsically language specific and therefore almost never accessible to translation. Punning is the skilled and creative native speakers' privilege and hallmark and consequently none of the foreigner's business.

Homophonous similarity functions with or without graphemic variation. The following are some examples:

(1) "How is bread made?" – "I know that", Alice cried eagerly, "you take some flour . . ." "Where do you pick the flower?" the White Queen asked . . . – "Well, it isn't picked at all", Alice explained: "it is ground . . ." – "How many acres of ground?" . . . (From Alice in wonderland; flour : flower)

(2) "if so 'tis the will of Whose B. Dun" (from Finnegan's wake, Joyce, 1975: 518).

In this case, the relative pronoun *whose* figures as part of a (homophonous, 'created') proper name (*Whose*).

Here is a psychological joke, in German, that was popular during World War II:

(3) First psychiatrist: "Heil Hitler!"
Second psychiatrist: "Heil du ihn!"
('Hail to Hitler!' – 'Heal him yourself!')

The joke stems from the fact that German *heil* can mean either 'hail' or 'heal'. In this example, moreover, we see how punning may transcend the boundaries of word categories, here noun versus verb.

A Turkish-based pun:

(4) 'Do you know the name of Michael Jackson's brother?'
'It's sikeceksin [djeksin]'

Here, Turkish *sik-* 'fuck' + suffix *–ecek* 'future' + pronominal ending 2.SING *-in* 'you' would be translated as 'you are going to fuck'. Thus, the proper name (*Jackson*) is played off against the grammatical suffixes *-(e)cek-sin*).

Finally, a Russian example:

(5) СПАСИТЕ НАШИ ШУТИ/АУШИ
spasite naši šuti/duši
'save our paunches/souls'

Here, the pun plays on the phonetic similarity of the Russian words for 'paunches' and 'souls'.

Sometimes, an aggressive undertone is noticeable in puns (more often than not, this represents an assault on a taboo, as in 'All men are cremated equal'). The aggression may not always be manifest: German *Familienbande* may be read as either 'family bonds' or 'family gang'.

Because they are predominantly interactive, puns (like those who deliver them, the punsters) depend on their audiences for their effect. The readiness on the recipients' part to take upon themselves the task of disambiguating obvious norm abuses and ambiguities is a *sine qua non* for enjoying the (possibly surprising) new insights arising from the punster's artful endeavor, just like what happens in satire: here, the alternate understanding of a pun has its highest effect if the pun borders on antonymy (*see* **Antonymy and Incompatibility**).

Although normal, everyday ambiguity can be said to be characteristic of all words and idioms (in this, seemingly replicating the inscrutability of reality itself), there have been conjectures and suggestions concerning not only the pun's jocular, but also its presumed cognitive potency, i.e., its mantic/divinatory effectiveness. Especially in cosmogonies and mythologies, but also in certain styles of literary and even scientific writing, the belief in the creative energy of puns, as revealing relations between words and their referents in reality, has been productive since time immemorial (cf. the portentous homonymy of *malum* ('apple(-tree)') and *malum* ('bad') in the punning context 'God planted a *malum* in Paradise').

Surrealist poetry (André Breton) and drama (Georges Ionescu) illustrate this belief in words as dictating thought (cf. also the surrealists' *écriture automatique,* 'automated writing'). Similarly, the great English 19th-century poet Gerard Manley Hopkins oeuvre "progresse[s] by double meaning" (Redfern, 1984: 74).

Overall, puns play a considerable role in literary products of different description, ranging from poetry (including limericks) all the way to commercial texts used in advertising. Imagery in dreams is another area where paronomastic maneuvers prevail; however, the 'logical' puns in dreams are not meant or taken as joking language, but as expressions denoting (subconscious or surreal) facts (*see* **Psychoanalysis and Language**). Finally, one may note that the propensity to punning varies in accordance with the stylistic conventions prevalent in different eras; thus, periods such as the Baroque or Romanticism (not to forget the times of Shakespeare) have excelled in punning in comparison to earlier or later times.

Sextil Puşcariu, one of the dominant figures in Romanian linguistics, was born on January 4, 1877 at Braşov in Transylvania, then under Hungarian rule. Like many Romanians of his generation, he pursued his university studies and began his research career in Western Europe. At the University of Leipzig (where he obtained his doctorate in 1899 for a dissertation on diminutive suffixes in Romanian), he studied under the Indo-Europeanist and Neogrammarian, Karl Brugmann (*see* **Brugmann, Karl (1849–1919)**), and, among others, under Gustav Weigand, who was already working on Romanian. Among his later teachers were, in Paris, Gaston Paris and Jules Gilliéron (*see* **Gilliéron, Jules (1854–1926)**) and, in Vienna, a specialist in Balkan history, Konstantin Jireček, and the eminent Romance philologist, Wilhelm Meyer-Lübke (*see* **Meyer-Lübke, Wilhelm (1861–1936)**). In 1904 he was appointed to a lectureship at the University of Vienna and in 1906 became professor of Romance philology at the University of Cernăuţi (Tchernowitz) in the Bucovina, then still part of Austria. After the reunification of Transylvania with Romania at the end of World

Sextil Puşcariu, one of the dominant figures in Romanian linguistics, was born on January 4, 1877 at Braşov in Transylvania, then under Hungarian rule. Like many Romanians of his generation, he pursued his university studies and began his research career in Western Europe. At the University of Leipzig (where he obtained his doctorate in 1899 for a dissertation on diminutive suffixes in Romanian), he studied under the Indo-Europeanist and Neogrammarian, Karl Brugmann (*see* **Brugmann, Karl (1849–1919)**), and, among others, under Gustav Weigand, who was already working on Romanian. Among his later teachers were, in Paris, Gaston Paris and Jules Gilliéron (*see* **Gilliéron, Jules (1854–1926)**) and, in Vienna, a specialist in Balkan history, Konstantin Jireček, and the eminent Romance philologist, Wilhelm Meyer-Lübke (*see* **Meyer-Lübke, Wilhelm (1861–1936)**). In 1904 he was appointed to a lectureship at the University of Vienna and in 1906 became professor of Romance philology at the University of Cernăuţi (Tchernowitz) in the Bucovina, then still part of Austria. After the reunification of Transylvania with Romania at the end of World

War I, Puşcariu moved to Cluj where he was appointed as the first Rector of the Romanian-language university and where he was to spend the rest of his career.

At Cluj, he founded the distinguished research institute *Muzeul limbii române* ('The Museum of the Romanian Language') and launched, and for many years edited, its journal, *Dacoromania*.

His interests were wide ranging (including *inter alia* the study of early Romanian literature), but it was in the fields of Romanian lexicography, linguistic geography, and dialectology (his first published work, dating from 1898, was an article on the dialect of the upper Olt valley) that he was most influential. Having published in 1906 the first (and only) volume of a Romanian etymological dictionary, he was entrusted in 1908 with the editorship of the Romanian Academy's dictionary (roughly comparable with the *Oxford English Dictionary*) of which three volumes appeared in his lifetime (the work is still not complete). Also still incomplete is the impressive linguistic atlas of Romania that Puşcariu launched and edited and of which three volumes appeared in his lifetime. Together with three collaborators (Bartoli, Belulovici, and Byhan) he published a three-volume study (including, *inter alia*, a volume of texts, a grammar, and a bibliography) of the now almost extinct Istro-Romanian dialect of northwestern Croatia. Only the first two volumes appeared (the second of them posthumously) of his projected general descriptive and historical study of the Romanian language. He died at Cluj on May 5, 1948.

Putnam, Hilary (b. 1926)

P H Portner, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Hilary Putnam (b. 1926) is one of the most influential philosophers of language of the 20th century. He made outstanding contributions to the study of language and linguistics through his work in philosophy of language and philosophy of mind; in addition, his work is significant in other areas of philosophy, such as philosophy of science. He was active in protests against the Vietnam war and in associated political movements.

Putnam received a Ph.D. from the University of California at Los Angeles in 1951 and then taught at Northwestern, Princeton, and MIT. He became part of the philosophy department at Harvard in 1976, later becoming the Walter Beverly Pearson Professor of Mathematical Logic, and remained there until he retired in 2000. His most important articles are collected in the three volumes of his *Philosophical papers*.

In philosophy of mind, Putnam is important as a founder of functionalism, the idea that mental states are defined in terms of their relations to the environment, other states, and behavior (Putnam, 1967). This perspective on the mind was important for the development of cognitive science, as it helped validate thinking of the mind as a kind of computing device, with the possibility of the same mental states existing in different physical systems. In later years, Putnam criticized his earlier functionalist views in a number of ways.

In philosophy of language, Putnam argued that meaning is not determined solely by the internal mental states of speakers, but instead crucially involves a relation to the external environment (Putnam, 1975a). He famously argued for this point with his 'Twin Earth thought experiments.' In these, one imagines an individual with exactly the same internal mental makeup as someone on Earth, but existing on a planet that differs from Earth only in that some aspect of the environment, say water, is replaced by a different substance with the same macroscopic properties. For such an individual, it's obvious that

War I, Puşcariu moved to Cluj where he was appointed as the first Rector of the Romanian-language university and where he was to spend the rest of his career.

At Cluj, he founded the distinguished research institute *Muzeul limbii române* ('The Museum of the Romanian Language') and launched, and for many years edited, its journal, *Dacoromania*.

Putnam, Hilary (b. 1926)

P H Portner, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Hilary Putnam (b. 1926) is one of the most influential philosophers of language of the 20th century. He made outstanding contributions to the study of language and linguistics through his work in philosophy of language and philosophy of mind; in addition, his work is significant in other areas of philosophy, such as philosophy of science. He was active in protests against the Vietnam war and in associated political movements.

Putnam received a Ph.D. from the University of California at Los Angeles in 1951 and then taught at Northwestern, Princeton, and MIT. He became part of the philosophy department at Harvard in 1976, later becoming the Walter Beverly Pearson Professor of Mathematical Logic, and remained there until he retired in 2000. His most important articles are collected in the three volumes of his *Philosophical papers*.

In philosophy of mind, Putnam is important as a founder of functionalism, the idea that mental states are defined in terms of their relations to the environment, other states, and behavior (Putnam, 1967). This perspective on the mind was important for the development of cognitive science, as it helped validate thinking of the mind as a kind of computing device, with the possibility of the same mental states existing in different physical systems. In later years, Putnam criticized his earlier functionalist views in a number of ways.

In philosophy of language, Putnam argued that meaning is not determined solely by the internal mental states of speakers, but instead crucially involves a relation to the external environment (Putnam, 1975a). He famously argued for this point with his 'Twin Earth thought experiments.' In these, one imagines an individual with exactly the same internal mental makeup as someone on Earth, but existing on a planet that differs from Earth only in that some aspect of the environment, say water, is replaced by a different substance with the same macroscopic properties. For such an individual, it's obvious that

the word 'water' would refer to the substance existing on Twin Earth, and not to water. But since the individual and his twin on Earth by hypothesis have the same internal mental makeup, this shows that meaning is not a purely internal matter.

Main Languages

The official language is Classical Arabic (Standard Arabic), while a diglossic situation exists with colloquial Arabic (Gulf Spoken Arabic) as the spoken medium. A long-standing link with Baluchistan and the Muslim populations of India means that many members of the older population have some knowledge of Baluchi (Balochi) or Urdu. Equally their trading links with Iran make Persian (Farsi) understood to various levels by many people. There are also considerable immigrant populations of different levels of antiquity from Persia and Baluchistan. None of these languages have any official status although Urdu was widely spoken in the police and armed forces at an earlier period.

Spoken Arabic Dialect

Historically, before the oil period many of the population mixed a seafaring life with a herding and agricultural one. The wealth of the country depended on pearling in previous centuries, while the town of Zubara flourished for 20 years as the main trading center of the Gulf in the late 18th century. The spoken dialects therefore show links with Central Arabia and with the coastal areas and Iran. Dialect is here mainly a marker of ethnic affiliation and in a very general sense one can distinguish the following:

1. The speech of Najdi clans who arrived since the 17th century, exemplified by the rulers, the Āl Thāni; also other Ma'āḍīd and the Hawājir and Nu'aim, who are sometimes grouped among the 'Utūb of the northern Gulf States;
2. The speech of the Hwilah, Arab groups who had moved to the Persian coast at an earlier period, but moved back since the 17th century. Similar also is the speech of other Persian populations of some antiquity;
3. The Āl Murrah bedouin, many of whom moved into Qatar over recent centuries, but retain a dialect akin to that of Najrān in Saudi Arabia.

Qimhi, David (1160–?1235)

H Y Sheynin, Gratz College, Melrose Park, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

David Qimhi (1160–?1235) was an outstanding Jewish biblical commentator, grammarian, and lexicographer, and the son of an illustrious family of grammarians (he was the son of Joseph Qimhi, author of two grammatical treatises, *Sēfer ha-zikkārōn* 'Book of remembrance' and *Sēfer gālūy* 'Open book', and brother to Moses Qimhi, author of the short grammar *Mahălakh šĕvīlē ha-da'at* 'Course of paths to the knowledge'). After the invasion of Andalusia by the Almohades in 1148, his father moved first to northern Castile and then to Provence. Qimhi was born and lived in Narbonne, where he worked as Hebrew teacher. In matters of the Hebrew language, he was a disciple of his older brother Moses, and in his works he continued the traditions of his family. By the time Qimhi started writing, major advances in research by scores of Spanish Jewish grammarians (10th–12th centuries) had been achieved. The main goal of this school was to improve understanding of the Hebrew bible. For this purpose, they adopted comparative Semitics as a method and produced a significant number of monographs devoted to particular topics. Since most of the works of this school were written in Judeo-Arabic, they were known predominantly to Jewish scholars of Muslim countries and unknown in Western Europe.

Qimhi wrote in Hebrew. His major work, in addition to an immensely popular commentary on the entire bible, was a large compendium, *Sēfer ha-mikhlōl* ('Book of perfection') which was divided to two books. The first was a grammar (which is usually called *Ḥēleq ha-diqdūq* or *Sēfer ha-mikhlōl*, i.e., 'Grammar's part' or 'Book of perfection') on phonology, morphology and syntax; the second was *Ḥēleq ha-'Inyān*, or *Sēfer ha-šŏrāšīm* ('Contents' part' or 'Book of roots', i.e., a dictionary). Both of these parts enjoyed tremendous popularity among Hebrew scholars and were printed already in the initial period of printing (the dictionary, since ca. 1469; the grammar, since 1532) and reprinted many times, especially the dictionary.

His minor grammatical works include *'Ēṭ sōfēr* ('The scribe's pen'), a grammatico-massoretic treatise about vocalization, cantillation, and rules of biblical orthography, that was known for long time in manuscripts, but published for the first time only in 1864; and a grammatical work, *Pētaḥ dĕvāray* ('Opening of my words'), a work of unclear attribution that some scholars ascribe to Qimhi.

To the particular Qimhi's innovations, one has to assign his classification of vowels, recognition of the *dāgēš lene* (i.e., variation of phonemes b/v, g/gh, d/dh, k/kh, p/f, t/th), discussion of assimilation of consonants, fixing the verb at the center of the grammar, treatment of verb formations, distinguishing of the *wāw* consecutive from the *wāw* conjunctive, and legitimizing of postbiblical developments. Qimhi systematized and completed linguistic study of the bible in the Middle Ages. He more than others is responsible for the formulation of principles of the grammar of the Hebrew language.

Qimhi's ingenious summary of 200 years of study of biblical Hebrew, and clear and systematic exposition of the material, made his works the authoritative reference of Hebrew linguistics. They were used for instruction and reference, commentated and popularized by later Jewish linguist Elijah Levita (*see* **Levita, Elijah (1469–1549)**), and they became a foundation for the study of biblical Hebrew by Christian Hebraists in the 15th and 16th centuries. Even Wilhelm Gesenius and his followers relied heavily on both Qimhi's grammar and dictionary.

Quakerism

P Anderson, George Fox University, Newberg, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Within the Radical Reformation of 17th-century England, the Religious Society of Friends (also known as Quakers) stands out for its connecting of speech and language to authentic and direct communication in their faith and practice. Friends opposed manipulations of language for ulterior reasons or coercive purposes. Central to their concern was the teaching of Jesus: "Let your yes be yes, and let your no be no."

Within their first generation (1652–1691), Friends opposed several leverage-related uses of language in Britain. Because *creedal expressions of faith* separated right believers from others on formalistic grounds, Friends testified that faithfulness to Christ and the Gospel are better measured by one's authentic religious experience and transformed life. Putting one's commitments in one's own words has greater authenticity and meaning than conforming to prescribed language. Likewise, rather than resorting to *directive liturgical words and patterns of worship*, Friends argued that the focus of the worshiper should be on the object of worship: God. In seeking to preserve authenticity of religious belief and expression, Friends not only sought to counter dead formalism, they also sought to challenge lively formalism – pointing instead to the inspiring activity of the Holy Spirit in the lives of believers.

Friends also opposed the manipulative use of language within society. Where *flattery* and *high-sounding platitudes* had become common means of social exchange, Friends refused to use titles and the more elevated plural 'you' for second-person singular references, substituting it with the more intimate 'thee' and 'thou'. Friends also refused to *swear loyalty* to the king, church, or nation. Most famous is William Penn's expulsion from Oxford in 1661 on the basis of his refusal to swear an oath of loyalty. A third convention challenged by Friends was the required *swearing to tell the truth* before a court of law. Friends cited Jesus's instructions not to swear either by heaven or by earth as the basis for their testimony, and they sought to let their 'Yes' mean yes and their 'No' mean no in the common ventures of life. In all these instances, integrity over image was the leading conviction, and Friends sought to make words an extension of authentic intention rather than manipulative rhetoric.

These convictions lend themselves to applications. In *worship*, Friends seek to exercise vocal ministry as led by the Holy Spirit within the gathered meeting. The prepared messenger is elevated over the prepared message, and women as well as men are welcome to speak. The personal testimonial is valued as an experiential account of one's pilgrimage in the Light, and the devotional journal has become a classic means of narrating one's story as a witness to divine grace and faithfulness. *Plain language and direct speech* continue as testimonies of Friends, and Friends largely forego the use of titles. *Inclusive language* is likewise employed by Friends, and they also disavow strong language, as it functions to yoke what is sacred or vulgar to rhetorical ploys. If the truth of a claim is insufficient, no one is helped by representing it otherwise. Truth-seeking, truth-finding, and truth-communicating are matters of first importance for Friends.

Modes of communication by Quakers are many. The sermons and pamphlets of early Friends are numerous, as are Friends journals over more than three centuries. Indeed, Quaker women have served as preachers and writers in addition to men, and for more than one reason Friends have been called 'Publishers of Truth.' Silence and plainness, however, should not be regarded as an obverse kind of informal formalism. Rather, they create the space to focus on the Divine Presence and Reality above all else. If there were a means of conveying the reality of the Spirit in physical means, Friends would testify that this locus of expression is *incarnational*. Christ is held to be sacramentally present in the gathered meeting for worship (Matt. 18:18–20), and his work is communicated to the world most effectively by means of the changed and changing lives of those who know his will and are responsive to it. These Jesus calls his "friends" (Jn. 15:14ff.). Thus, for Friends, the communicative venture endeavors to connect the divine source of Truth with that which is open to it in others. George Fox (*Journal*, 1656) put it this way:

> Let all nations hear the word by sound or writing. Spare no place, spare not tongue nor pen, but be obedient to the lord God and go through the world and be valiant for the Truth upon the earth . . .. Be patterns, be examples in all countries, places, island, nations, wherever you come, that your carriage and life may preach among all sorts of people, and to them; then you will come to walk cheerfully over the world, answering that of God in every one.

Quantifiers: Semantics

E L Keenan, University of California, Los Angles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

During the past 25 years, our empirical and mathematical knowledge of quantification in natural language has exploded. We now have mathematically precise (if sometimes contentious) answers to questions raised independently within generative grammar, and we are able to offer many new generalizations. We review these results here. For extensive overviews, see Westerståhl (1989), Keenan (1996), and Keenan and Westerståhl (1997). Some important collections of articles are van Benthem and ter Meulen (1985), Reuland and ter Meulen (1987), Gärdenfors (1987), Lappin (1988), van der Does and van Eijck (1996), Szabolcsi (1997), and from a mathematical perspective, Krynicki *et al.* (1995).

The best understood type of quantification in natural language is that exemplified by *all poets* in *All poets daydream*. We treat *daydream* as denoting a property of individuals, represented as a subset of the domain E of objects under discussion. Quantified Noun Phrases (NPs) such as *all poets* will be treated as denoting functions, called 'generalized quantifiers,' which map properties to truth values, True (**T**) or False (**F**). For example, writing denotations in boldface, **all poets** maps **daydream** to True (over a domain E) if and only if the set of poets is a subset of the set of objects that daydream. Interpreting Dets (Determiners) as functions from properties to generalized quantifiers, we give denotations for many quantifiers in simple set theoretical terms. We write $X \subseteq Y$ to say "X is a subset of Y," $X \cap Y$ for "X intersect Y," the set of objects that lie in both X and Y; $X - Y$ for the set of objects in X that are not in Y, and $|X|$ for the number of elements in X.

(1a) **ALL**(A) (B) = **T** iff $A \subseteq B$
(1b) (**THE TEN**) (A) (B) = **T** iff $|A| = 10$ and $A \subseteq B$
(1c) **NO**(A) (B) = **T** iff $|A \cap B| = 0$
(1d) **SOME**(A) (B) = **T** iff $|A \cap B| > 0$
(1e) **NEITHER**(A) (B) = **T** iff $|A| = 2$ & $|A \cap B| = 0$
(1f) (**FEWER THAN TEN**) (A) (B) = **T** iff $|A \cap B| < 10$
(1g) (**ALL BUT ONE**) (A) (B) = **T** iff $|A - B| = 1$
(1h) **MOST**(A) (B) = **T** iff $|A \cap B| > |A - B|$

To test that the definitions above have been properly understood, the reader should try to fill in appropriately the blanks in (2).

(2a) (**AT LEAST TWO**) (A) (B) = **T** iff ____
(2b) **BOTH**(A) (B) = **T** iff ____
(2c) (**AT MOST FIVE OF THE TEN**) (A) (B) = **T** iff ____
(2d) (**LESS THAN HALF THE**) (A) (B) = **T** iff ____

We concentrate on NPs of the form [Det + N], but we should point out three further classes of generalized quantifiers denoting NPs: first, lexical NPs, notably proper nouns such as *John* and *Mary*; second, boolean compounds in *and*, *or*, *neither* . . . *nor* . . . and *not*, as in *Neither John nor Mary* (came to the party), *Sue and some student* set up the chairs, *not more than two students* attended the lecture. And third, NPs built from Dets that combine with two Nouns to form an NP (Keenan and Moss, 1985; Beghelli, 1993): *more students than teachers* (signed the petition), *exactly as many students as teachers* signed, etc. The interpretation of *more* . . . *than* . . . is given by:

(3) For all properties A,B,C (**MORE** A **THAN** B) (C) = **T** iff $|A \cap C| > |B \cap C|$

The reader may want to write out the definitions of two place Dets such as **FEWER** . . . **THAN** . . ., **TWO MORE** . . . **THAN** . . . , **TWICE AS MANY** . . . **AS** . . . , **THE SAME NUMBER OF** . . . **AS** . . .

Standard Quantifiers: Some Linguistic Generalizations

We consider cases where the quantifier semantics sketched above has proven enlightening in formulating linguistic generalizations. As a first case, observe that in (4a) the presence of *ever*, called a 'negative

Standard Quantifiers: Some Linguistic Generalizations

We consider cases where the quantifier semantics sketched above has proven enlightening in formulating linguistic generalizations. As a first case, observe that in (4a) the presence of *ever*, called a 'negative

polarity item (npi),' is ungrammatical; in (4b) it is fine.

(4a) *Some student here has ever been to Pinsk.
(4b) No student here has ever been to Pinsk.

Similarly *any* in *No child saw any birds on the walk* is an npi, not licensed in **Some child saw any birds on the walk*. **The linguistic query:** Which NPs in contexts like (4) license npi's? To within a good first approximation, the answer is given by the Ladusaw-Fauconnier Generalization (Ladusaw, 1983): *The NPs which license npi's are just those which denote decreasing (order reversing) generalized quantifiers*. A generalized quantifier F is *decreasing* iff whenever $A \subseteq B$ then if $F(B) = \mathbf{T}$ then $F(A) = \mathbf{T}$. **No student** is decreasing since if all As are Bs ($A \subseteq B$), then if no student is a B, it follows that no student is an A (otherwise that student would also be a B, contrary to assumption). In contrast, **some student** is not decreasing: perhaps all As are Bs and there are many students among the Bs but they all lie among those that are not As. The reader can verify that the following NPs are decreasing and do license npi's: *fewer then five students*, *less than half the students*, *not more than two students*, *neither John nor Bill*, *no student's doctor*. In contrast, NPs such as *John*, *more than five students*, *most poets*, *either John or Bill*, *some student's doctor* are not decreasing and do not license npi's. Keenan and Szabolcsi (*see* **Boole and Algebraic Semantics**) point out that standard negation is also a decreasing function, and it also licenses npi's: **John has ever been to Pinsk* vs. *John hasn't ever been to Pinsk*.

Our first generalization also illustrates that whether an NP of the form [Det + N] is decreasing or not is decided by the Det. So if *no student* is decreasing then, so is *no child*, *no professional acrobat*, etc. since they all have the same Det. Similarly if *some student* is not decreasing, then neither is *some child*, *some professional acrobat*, etc., Many linguists refer to the expressions we call NPs as DPs ('Determiner Phrases'), in part because significant properties of the entire expression, such as whether it is decreasing or not, is decided by the choice of Det. (But other properties, such as whether the expression is animate, feminine, or satisfies the selection restrictions of a predicate, are determined by the N. #*Every idea laughed* is bizarre, since ideas aren't the kinds of things that can laugh and changing the Det does not improve matters: #*Some idea laughed*, #*Most ideas laugh*).

As a second generalization, consider how we may characterize the NPs that are *definite* (plural) in the sense that they may grammatically replace *the poems* in *two of the poems*. Some such NPs are *the ten poems*, *these (ten) cats*, *John's (ten) students*. Some NPs that are not definite (plural) in this sense are: *no poems*, *every cat*, *most students*. Again, to within a first approximation, we may say that the definite plural NPs are those of the form [Det + N], where (in each domain) Det denotes a function f that satisfies:

(5) For all A, either $f(A)(B) = \mathbf{F}$; all B, or for some $X \subseteq A$, $f(A)(B) = \mathbf{T}$ iff $X \subseteq B$.

To illustrate the idea, **(John's ten) (students)** maps each set **B** to **F** if John does not have exactly ten students; if he does, then it maps a set B, such as **daydream in class** to **T** iff the property of being a student-which-John-has is a subset of B. See Barwise and Cooper (1981) and Matthewson (2001) for further discussion.

The two generalizations adduced so far are semantic characterizations of syntactic phenomena. For purposes of defining the class of well-formed expressions in English, we need to know which NPs license npi's in the predicate and which may occur naturally in the post *of* position in partitives. Most approaches to generative grammar desire a purely syntactic definition of these classes. Our observations do not rule out such definitions. Indeed, they provide a criterion for whether a proposed definition is adequate or not. Still, at the time of writing, we have no explicit syntactic definition of these two classes of NPs.

A third problem comparable to our first two is to characterize those NPs that occur naturally in *Existential There* (ET) contexts, as in (6).

(6a) There are/aren't *more than ten boys* in the room.
(6b) *There are/aren't *most boys* in the room.

This problem has vexed generative grammarians since Milsark (1977). See Reuland and ter Meulen (1987) and Keenan (2003). Part of the problem is that affirmative declarative Ss of the form in (6) have a variety of uses, with different uses seemingly allowing different NPs. For example, in so-called 'list contexts' (Rando and Napoli, 1978), ET sentences admit definite NPs such as *the bus* in *How can I get to UCLA from here? Well, there's always the bus, but it doesn't run very often*. But mostly these uses are not preserved in negative or interrogative Ss. Putting aside uses limited to affirmative declarative Ss, Keenan (2003) supports that NPs that occur freely in ET contexts are ones built from Dets that denote a certain kind of 'conservative' function. A Det is, standardly, **conservative**, or as we shall say here, **conservative on its first argument**, if it satisfies (7a), stated more generally in (7b).

(7a) Det poets daydream iff Det poets are poets who daydream
(7b) $D(A)(B) = D(A)(A \cap B)$

To see that *most but not all* is conservative, for example, check that *Most but not all poets daydream* and *Most but not all poets are poets who daydream* always have the same truth value. Indeed, the second sentence seems redundant, with the predicate just repeating information already contained in the Noun argument.

The formulation in (7b) says that in evaluating the truth of D(A) (B), we may limit the predicate argument B to those of its elements that occur in A. In this sense, then, we shall say that D is CONS1, 'conservative on its first argument.' And we support:

(8) **Cons** in general Dets denote CONS1 functions

Cons is a new generalization, not one that arises directly in response to a query from independent linguistic study. It is surprisingly strong. Given a domain E with n elements, Keenan and Stavi (1986) show that for $k = 4^n$ there are 2^k functions from pairs of properties to {**T**,**F**}. Only $2^{k'}$ of these functions are **Cons**, where $k' = 3^n$. So in a domain with just two individuals, there are $2^{16} = 65\,536$ maps from pairs of properties to truth values, only $2^9 = 512$ of which are conservative! So **Cons** rules out most logically possible denotations for Dets. Here is a simple non-conservative function, F: F(A) (B) = **T** iff |A| = |B|. Clearly F({a,b},{a,c}) = **T**, but F({a,b},{a,b} ∩ {a,c}) = F({a,b}{a}) = **F**, so F fails **Cons**.

Now, mathematically it makes sense to ask whether there are Dets that are conservative on their second, predicate, argument. Such Dets would denote functions D satisfying D(A) (B) = D(A ∩ B) (B), where we can limit the As we consider to those that lie in B. Many natural classes of Dets fail CONS2. For example, **universal** Dets, such as *all*, *all but ten*, *every . . . but John*. It might be false that all poets daydream, but it must be true that all poets who daydream daydream. So *all* is not CONS2. Also not CONS2 are **definite** Dets, such as *the*, *the ten*, *these (ten)*, *John's (ten)*; and **proportional** Dets, such as *most*, *half (of) the*, and *not one . . . in ten*. But there is one large class of Dets that are CONS2. They include the *intersective* Dets, ones whose values just depend on which objects have both the Noun property and the Predicate property. For example, *some* is intersective since the truth of SOME(A) (B) is decided just by checking A ∩ B (verifying that it is not empty). Let us define:

(9) D is *intersective* iff for all A, A′, B, B′ if A ∩ B = A′ ∩ B′ then D(A) (B) = D(A′) (B′)

So intersective Ds are ones 'invariant' under replacement of A and B with other arguments A′ and B′ provided the intersection of the pairs of arguments remains unchanged. Note that, an intersective D is necessarily CONS 1: since A ∩ B = A ∩ (A ∩ B) we infer D(A) (B) = D(A) (A ∩ B). And since A ∩ B = (A ∩ B) ∩ B, we have that D(A)(B) = D(A ∩ B)(B), and so intersective Dets are CONS2. In fact:

Theorem D is intersective iff D is CONS1 and CONS2 (Keenan, 2003)

An important special case of intersective Dets are **cardinal** ones, whose values depend on the cardinality of A ∩ B, such as *at least n*, *more/fewer than n*, *at most n*, *approximately n*, *between n and m*, *several*, *a dozen*, *just finitely many*, and *infinitely many*. And we now answer our third query (Keenan, 2003):

(10) NPs which occur freely in Existential There contexts are (boolean compounds of) ones built from CONS2 Dets.

'Boolean compounds' here just refers to NPs built by conjunction, disjunction, and negation. For example, *There are at least two dogs and not more than five cats in the garden* is fine since *at least two dogs* and *more than five cats* both occur in ET contexts.

Example (10) predicts that NPs built from intersective Dets occur in ET contexts, and this is correct: *Aren't there between five and ten students in your class*? *Was there no student (but John) in the building*? etc. (Note that **no . . . but John** treated as a Det is intersective, as *No A but John is a B* is True iff A ∩ B = {John}, that is, the only A that is a B is John). Similarly, the universal, definite, and proportional Dets noted earlier are predicted not to occur freely in ET contexts since they fail CONS2, and this is correct: **Weren't there all/most/the students in the class*?

Are there are CONS2 Dets that fail to be intersective? By the theorem, they would have to fail to be CONS1, and so rather rare. But there are two candidates: NPs of the form [only/mostly N], such as *only poets*. Interpreting *only* as a Det yields ONLY(A) (B) = **T** iff B ⊆ A. For example, *Only poets daydream* is true iff everyone who daydreams is a poet (but there may be poets who don't daydream). Clearly ONLY thus defined is CONS2, since ONLY(A ∩ B)(B) = **T** iff B ⊆ A ∩ B, iff B ⊆ A. So (10) predicts the well-formedness of *There weren't only poets at the party*, which is correct.

A last case covered, unexpectedly, by (10) are NPs built from comparative Dets like *more . . . than. . .* which combined with two Ns to form an NP. Each N property is a conservativity domain. To evaluate whether *More students than teachers daydream* we must consider both the students who daydream and the teachers who daydream. But not only are comparative NPs conservative on their two N arguments; they are intersective, in fact, cardinal. To decide whether more As than Bs have C, we need only check |A ∩ C| and |B ∩ C|, verifying that the

former is greater than the latter. Thus, (10) predicts that cardinal comparatives should occur in ET contexts, and they do: *Weren't there more students than teachers at the party*? (We can also compare predicate properties, as in *More poets drink than smoke*, in which case only the single N property is a conservativity domain).

A fourth linguistic generalization is given in (11), where 'lexical' means 'not syntactically derived.'

(11) Lexical NPs are monotonic, and lexical Dets build monotonic NPs.

A monotonic NP is one that either denotes a decreasing function (already defined) or an increasing one, where a generalized quantifier F is **increasing** iff whenever $A \subseteq B$ then if $F(A) = \mathbf{T}$ then $F(B) = \mathbf{T}$. Lexical NPs, principally proper nouns (*John*, ...) and pronouns (*he*, *she*, ...), are easily seen to be increasing: to paraphrase Aristotle, if all poets daydream and Paul is a poet then Paul daydreams. The reader may verify that *all/some/most/the five/my/John's cats* are all increasing, so lexical Dets usually build increasing NPs. But *no* and *neither* build decreasing ones. The only slightly doubtful case are NPs built from bare numerals, such as *two poets*. The NP is increasing if *two* is understood in the sense of *at least two*; it is not monotonic if understood as *exactly two*. We find the *at least two* reading the most natural because in some cases that is clearly what is intended, as in *Are there two free seats in the front row*? Additional information from context can be invoked to force the *exactly two* reading. Our last generalization in this section is (12):

(12) Natural Language Dets are Domain Independent

In practical applications, such as in database theory (Abiteboul *et al.*, 1995), it is important to know what the domain of objects is that properties under consideration are subsets of. It would be more accurate (van Benthem, 1984) to treat NPs, for example, as functions that associate with each possible domain E a generalized quantifier over E, a function associating with each subset A of E a truth value. Similarly Dets associate with each E a function mapping subsets of E to generalized quantifiers over E. But (12) says that the value a Det denotation D assigns to a pair A, B of properties cannot depend on the choice of underlying domain (as long as A and B are subsets of that domain). This (seemingly vacuous) constraint entails, for example, that natural languages could not present a Det *blik* defined by: *Blik As are Bs* is True iff the number of non-As is two. The truth value of such an S would vary with the domain: if $A = \{a\}$ and $E = \{a,b,c\}$ then it is True, but if $E = \{a,b\}$ it is False.

To close this section, we note that our treatment of NPs and Dets enables us to specify precisely certain traditional, if informally given, classes of expressions. We note two cases. First, the linguistic literature on quantification usually builds heavily on the specific quantifiers *some* and *all*, which we have already defined. But now we can see that they represent two quite general classes of Dets: the *Existential* ones, including *some*, are just those that denote intersective functions, as defined in (9). The *Universal* Dets are those that denote cointersective ones, as defined in (13).

(13) D is *co-intersective* iff for all A, B, X, Y if $A - B = X - Y$ then $D(A)(B) = D(X)(Y)$

Thus, whether a cointersective function D is True of a pair A,B is decided just by checking $A - B$. To see that ALL is cointersective observe that, as defined, $ALL(A)(B) = \mathbf{T}$ iff $|A - B| = 0$. (ALL BUT TEN) (A) (B) $= \mathbf{T}$ iff $|A - B| = 10$, etc. Our approach also enables us to see that proportionality Dets such as *most*, *half*, *more than one ... in ten*, etc., are more complicated than either intersective or cointersective Dets, because their truth at a pair A, B of properties depends on both $A \cap B$ and $A - B$.

Secondly, most of the Dets discussed in the linguistic literature are ones with a 'logical' or 'mathematical' sense: *some*, *every*, *most*, *most of the ten*, *not all*, *most but not all*, *between a third and two thirds of the*, etc. But we have also countenanced a few which are more 'empirical', such as *my*, *John's ten*, *no ... but John*, etc. (see Keenan, 1996). Can we say in precise terms what the distinction is? We can. The logical' Dets are those that are invariant under permutations of the elements of the underlying domain E. A permutation of E is simply a one-to-one function from E onto E. If h is such a function and A a subset of E, then by h(A) is meant $\{h(x) | x \text{ in } A\}$. And we say that a generalized quantifier F is *permutation invariant* (PI) iff for all A, all permutations h of E, $F(A) = F(h(A))$. A Det function D is PI iff for all A,B and all permutations h, $D(A)(B) = D(h(A))(h(B))$. Note that, for any $X \subseteq E$, X and h(X) always have the same cardinality. So the 'logical' quantifiers are those that cannot distinguish between properties A, A′ of the same cardinality (and whose complements, $E - A$ and $E - A'$ have the same cardinality when E is infinite). One computes, then, that Dets such as *some*, *every*, *most*, *most of the ten*, *not all*, *most but not all*, *between a third and two thirds of the* always denote PI functions, whereas ones like *my*, *John's ten*, etc., do not.

Some Non-Standard Quantifiers

We begin by considering the interpretation of the quantified NPs already discussed when they occur as

objects of transitive and ditransitive verbs: *John envies all movie actors*, *He gave most of his teachers several presents*. Many semanticists regard these uses as illustrating a 'type mismatch.' To interpret the object NP in *John interviewed every applicant* we apparently need to treat it as a function mapping a binary relation (**interview**) to a property, but we are already committed to interpreting NPs as maps from properties (unary relations) to truth values (zero-ary relations). But in fact there is no problem here at all. We know exactly what property *interviewed every applicant* denotes. It is the set of objects x such that 'x interviewed every applicant', that is, such that **every applicant** is true of the *set* of objects that x interviewed. In the last phrase, we are applying the generalized quantifier **every applicant** to a set – which is exactly how we have already been interpreting NPs. So the value that an NP denotation assigns to a binary (ternary, . . .) relation is determined by the value that it assigns to sets (properties). So the solution to the 'type mismatch' problem is to treat NPs as directly denoting functions mapping n+1-ary relations to n-ary ones in such a way that their values at $n > 1$-ary relations are determined by their values at the unary relations. Here is the solution for binary relations. Keenan and Westerståhl (1997) give the general statement. We write aR for {b|aRb}, the set of objects that a stands in the relation R to.

(14) A type <1> function F over a universe E maps each subset of E to a truth value and each binary relation R over E to a subset of E by: $F(R) = \{a|F(aR) = \mathbf{T}\}$.

Clearly, then, each generalized quantifier uniquely determines a type <1> function; all we have done is add more objects (binary relations) to its domain. So the interpretation of an S with two quantified NPs is given compositionally, as in (15).

(15a) No politician kissed every baby
(15b) (**no politician**) ((**every baby**) (**kissed**))

Note that, (15b) means 'No politician has the property that he kissed every baby,' the object narrow scope (ONS) reading of (15a). In fact, (15a) does not have an object wide scope (OWS) reading, on which it would mean that every baby has the property that no politician kissed him. But some Ss with two quantified NPs do present such ambiguities, a matter of much concern to linguists (Szabolcsi, 1997). *Some editor read every manuscript* has an ONS reading, representable analogously to (15b), on which it means that there is an editor with the property that he read every ms. But it also has a OWS reading, on which it means that every ms has the property that some editor read it – so the editors may vary with the manuscripts. An easy use of variable binding operators (VBOs) allows us to represent the less accessible OWS reading by:

(16) (**every manuscript** x) ((**some editor**) (**read** x))

The use of VBOs has distracted us from the fact that the range of logically possible interpretations of nonsubject NPs is vastly greater than of subject NPs. Given a universe E with more than one element, there are many more functions from binary relations to properties than there are from properties to truth values. And natural languages provide the means for denoting some of these. To see this, we need a way to test functions H from relations to properties to see if they are possibly extensions of functions from properties to truth values. Here is such a test, given first by example, where we test X:

(17a) If John praised exactly the people who Bill criticized then John praised X iff Bill criticized X
(17b) If $aR = bS$ then $a \in F(R)$ iff $b \in F(S)$

For example, *most of the Peter's students* passes the X test in (17a). Given the truth of the *if*-clause, we infer that *John praised most of Peter's students* and *Bill criticized most of Peter's students* have the same truth value. (This is hardly surprising; the NP we are testing occurs as a subject of a P1 and thus is interpretable as a generalized quantifier.)

But consider now the reflexive pronoun *himself*. It fails the test. Imagine, for example, that the *if*-clause is true and that John praised just Sam, Frank, Bill, and Sue. Then those are just the people that Bill criticized, so *Bill criticized himself* is true, but *John criticized himself* is false. Hence, there is *no* function from properties to truth value that takes exactly the value on binary relations as **himself** does. That is, reflexives represent an increase in logical expressive power. Moreover *himself* is not unique here; all (nontrivial) referentially dependent NPs in object position are logically new in this sense. This includes ones like *everyone but himself*, *both himself and the teacher*, *everyone smarter than himself* (as in *John criticizes everyone smarter than himself*) in which the NP must be referentially dependent, as well as NPs like *his mother* where it simply may be dependent. It is the dependent interpretation where it is new.

The increase in logical expressive power afforded by nonsubject NPs is far more extensive than instantiated by the referentially dependent NPs. They are not functions of type <1>, but they can be correctly interpreted as functions from binary relations to sets, (just not ones that extend appropriately a generalized quantifier). But the sort of dependency in (18) cannot be handled in a comparable way:

(18) Different people like different things

The weakest truth conditions of (18) are easy to state: for any two (different) people x and y, the set of things that x likes is not identical to the set that y likes. And we know (Keenan, 1996) that over any domain with several people and things, there are *no* type <1> functions F and G such that for all binary relations R, F(G(R)) is true iff different people stand in the relation R to different things. Similar claims hold for other Ss which involve comparing different object sets with different choices of subject argument: *John and Bill support rival political parties*, *Rosa and Zelda date men who dislike each other*, etc. In fact, the same claim holds even when the comparison is not one of difference: *All the students answered the same questions on the exam*, *They wore the same color necktie*, etc. Speaking very informally, we can say that the combination of subject and object expressions in these Ss place conditions on the relation denoted by the transitive verb which are inherently 'relational,' not expressible as independently statable conditions on each argument. To state this more explicitly, let us define:

(19) A function H from binary relations to truth values is said to be of type <2>. Such a function is type <1> *reducible* iff there there are type <1> functions F,G such that for all binary relations R, H(R) = F(G(R)).

Then what we are saying above is that the type <2> functions expressed by (Different people, different things), (John and Bill, rival political parties), etc., are not type <1> reducible. Thus, they are not expressible as the composition of two generalized quantifiers, and so are logically new. Some additional examples are induced by the *else-else* construction in (20), the *which-which* construction in (21), reciprocal objects in (22), and predicate anaphors in (23). For further examples, see Keenan (1996).

(20) John didn't praise Bill but everyone else praised everyone else.
John praised Bill but no one else praised anyone else.

(21) John doesn't know which students answered which questions on the exam.

(22) The students were shouting at each other.

(23) John read more books than Bill (did).

In sum, we have a list of expression types that are not type <1> reducible, but we do not know precisely what type <2> functions are expressible. All of them (over finite E)?

Thus, much remains to be discovered even in English, the language in which quantifiers have been the most extensively studied. And we are really just beginning to study quantification in less well known languages (Bach *et al.*, 1995; Matthewson, 2001) as well as in contexts other than that of NPs and Dets, the most prominent here being temporal and event quantification, using adverbial quantifiers, as in *Matt always/often/occasionally/seldom/rarely/never visits museums on weekends* (de Swart, 1996).

Answers to Exercises
(**AT LEAST TWO**) (A) (B) = **T** iff $|A \cap B| \geq 2$
BOTH(A) (B) = **T** iff $|A| = 2$ and $A \subseteq B$
(**AT MOST FIVE OF THE TEN**) (A) (B) = **T** iff $|A| = 10$ and $|A \cap B| \leq 5$
(**LESS THAN HALF THE**) (A) (B) = **T** iff $|A \cap B| < |A|/2$

Quantity

B Hermans, Tilburg University, Tilburg, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

In many languages, quantity has a contrastive function. In languages of this type, certain segments behave phonologically as if they really are two segments. These segments contrast with qualitatively identical segments that behave phonologically as single segments. An example of a language with a quantity contrast among vowels, as well as consonants is Luganda (Ganda). This is illustrated by the following words, taken from Katamba (1989).

(1)

phonological form	phonetic realization	
/kula/	[kula]	'grow up, IMP.'
/kuula/	[ku:la]	'uproot, IMP.'
/ta/	[ta]	'release, IMP.'
/tta/	[t:a]	'kill, IMP.'

In the majority of these languages, the phonological contrast between double (geminate) segments and single segments is phonetically implemented as a contrast between segments with greater duration versus segments with shorter duration. One of the languages where this is the case is Luganda, as shown by the examples above. This should not be taken to mean that in these languages a geminate segment is always phonetically longer than a corresponding single segment by a fixed amount of time, since there are many factors that influence phonetic duration. Some of the more important phonetic factors are the following: all else being equal, lower vowels are longer than higher vowels (Lehiste, 1970); vowels in open syllables are longer than vowels in closed syllables (Maddieson, 1985); vowels preceding voiced consonants are longer than those preceding voiceless consonants (Chen, 1970); vowels preceding fricatives are longer than vowels preceding stops (House, 1961); stressed vowels are longer than unstressed ones (Beckman *et al.*, 1992). Given these complicating factors, it can happen that a phonological geminate is realized with only little more phonetic length, or even less phonetic length, than a phonologically simple segment.

In almost all cases, the quantity contrast is binary. Apparent examples of ternary contrasts can almost always be reduced to a binary contrast by one of the phonetic tendencies listed above. Thus, in Estonian the third consonantal quantity is really a phonologically geminate consonant that is phonetically lengthened in a stressed syllable (Lehiste, 1966; Prince, 1980). Another, particularly convincing case is KiKamba (Kamba). Roberts-Kohno (1995) shows that in this language, the multiple quantity degrees attested on vowels can be reduced to a binary contrast by a system of phonetic lengthening rules. Yet apparently not all multiple quantity degrees can be reduced to a binary contrast. Ladefoged and Maddieson (1996) agree with Hoogshagen (1959) that Mixe is a language with a ternary quantity contrast on vowels.

In the classical generative literature (Chomsky and Halle, 1968), quantity was represented with the binary feature [long]. It soon became clear that this representation is wrong because it cannot capture the most fundamental property of geminate sounds, which is that they behave as a sequence of two single segments with respect to many phonological phenomena. This general phenomenon can take many specific forms. Some of the most frequent

In many languages, quantity has a contrastive function. In languages of this type, certain segments behave phonologically as if they really are two segments. These segments contrast with qualitatively identical segments that behave phonologically as single segments. An example of a language with a quantity contrast among vowels, as well as consonants is Luganda (Ganda). This is illustrated by the following words, taken from Katamba (1989).

(1)

phonological form	phonetic realization	
/kula/	[kula]	'grow up, IMP.'
/kuula/	[ku:la]	'uproot, IMP.'
/ta/	[ta]	'release, IMP.'
/tta/	[t:a]	'kill, IMP.'

In the majority of these languages, the phonological contrast between double (geminate) segments and single segments is phonetically implemented as a contrast between segments with greater duration versus segments with shorter duration. One of the languages where this is the case is Luganda, as shown by the examples above. This should not be taken to mean that in these languages a geminate segment is always phonetically longer than a corresponding single segment by a fixed amount of time, since there are many factors that influence phonetic duration. Some of the more important phonetic factors are the following: all else being equal, lower vowels are longer than higher vowels (Lehiste, 1970); vowels in open syllables are longer than vowels in closed syllables (Maddieson, 1985); vowels preceding voiced consonants are longer than those preceding voiceless consonants (Chen, 1970); vowels preceding fricatives are longer than vowels preceding stops (House, 1961); stressed vowels are longer than unstressed ones (Beckman *et al.*, 1992). Given these complicating factors, it can happen that a phonological geminate is realized with only little more phonetic length, or even less phonetic length, than a phonologically simple segment.

In almost all cases, the quantity contrast is binary. Apparent examples of ternary contrasts can almost always be reduced to a binary contrast by one of the phonetic tendencies listed above. Thus, in Estonian the third consonantal quantity is really a phonologically geminate consonant that is phonetically lengthened in a stressed syllable (Lehiste, 1966; Prince, 1980). Another, particularly convincing case is KiKamba (Kamba). Roberts-Kohno (1995) shows that in this language, the multiple quantity degrees attested on vowels can be reduced to a binary contrast by a system of phonetic lengthening rules. Yet apparently not all multiple quantity degrees can be reduced to a binary contrast. Ladefoged and Maddieson (1996) agree with Hoogshagen (1959) that Mixe is a language with a ternary quantity contrast on vowels.

In the classical generative literature (Chomsky and Halle, 1968), quantity was represented with the binary feature [long]. It soon became clear that this representation is wrong because it cannot capture the most fundamental property of geminate sounds, which is that they behave as a sequence of two single segments with respect to many phonological phenomena. This general phenomenon can take many specific forms. Some of the most frequent

instantiations involve tonal processes, foot structure, and syllable structure.

From a tonological point of view, geminate segments are often identical to a sequence of two segments. In Hausa, for instance, a falling tone can only appear in a syllable containing two segments (neglecting prevocalic consonants). Quite typically, it can also appear in syllables with a long vowel, and in a syllable with a short vowel followed by a long consonant. This indicates that long segments (vowels and consonants) are phonologically geminates; they count as a sequence of two segments. The following examples are taken from Newman (1995). In these examples, the first syllable has a falling tone; the second syllable has a high tone.

(2) mântáa 'forget'
yâaráa 'children'
shâddáa 'latrine'

Similar patterns are attested in many languages. Thus, Kenstowicz (1994) demonstrates that, from a tonal point of view, in Makua (Makhuwa) a long vowel behaves as a sequence of two syllables with short vowels. Furthermore, Kenstowicz (1970) demonstrates that in Lithuanian long vowels and short vowels followed by a tautosyllabic consonant can have the same tone patterns. Similar arguments have been presented in Woo (1969).

Also with regard to foot structure, long vowels and consonants form a natural class with a sequence of two segments. Thus, in the weight-sensitive feet, the even moraic trochee, the uneven moraic trochee, and the iamb, a foot's unstressed syllable must be light (Hayes, 1995). Very often this entails that this syllable may not contain two segments, counting from the vowel. Quite typically, it also implies that no long vowels or long consonants may be located in the foot's unstressed syllable. One of the many languages where this pattern is attested is Latin. This language has an uneven trochee that is built at the right side of a word, neglecting the final syllable, which is extrametrical. Thus, in Latin the following words are well formed, because the foot's unstressed syllable (the penult syllable) satisfies all conditions. In these examples, taken from Hayes (1995), foot structure is indicated with brackets.

(3) inimi:(kíti)a 'hostility'
(símu)la 'similate-2 SG.IMP'
do(mésti)kus 'belonging to the house'

On the other hand, in the following words stress may not be located on the antepenult syllable. If it could, the unstressed syllable of the foot would contain a heavy syllable. The stress must therefore be located on the penult syllable.

(4) orna(mén)tum 'equipment'
a(mí:)kus 'friend'
mi(tél:)a 'head band'

Again these facts show that a sequence of two segments, such as *en* in *ornamentum*, patterns with long vowels and consonants, indicating that they constitute a natural class.

Syllable structure also indicates that long segments should be treated as geminates phonologically. In many languages, there is an upper limit to the number of segments located in one and the same syllable. In Dutch, for instance, a short vowel may be followed by maximally two consonants in the same syllable, neglecting the coronal consonants *t* and *s*. In this language, a syllable's maximal size is three segments, one could say (neglecting the segments preceding the vowel). Typically, a long vowel may be followed by just one consonant in the same syllable. This is expected if long vowels are treated as geminates. Under this assumption, a long vowel occupies two positions in the syllable, so that there is room for just one other segment (cf. Trommelen, 1983 and van der Hulst, 1984; cf. van Oostendorp, 1995 for an alternative). The following examples illustrate the complementary distribution between long vowels and consonant clusters in Dutch.

(5) ram 'ram'
ramp 'disaster'
raam 'window'
*raamp

Similar effects can be found in many other languages. Japanese, for instance, allows maximally two segments in a syllable (neglecting the prevocalic consonants) (Itô, 1986; Vance, 1987). Typically, long vowels cannot be followed by a consonant in the same syllable.

All these phenomena have led phonologists to the conclusion that the feature [long] is wrong. It must be replaced by a representation that can express the fact that long segments behave as two segments. The first, obvious attempt was to represent a long segment as a sequence of two identical segments, as in Kenstowicz (1970). It is clear, however, that this cannot be correct either. The reason is that there are also many phenomena indicating that long segments do **not** behave as a sequence of two segments. To give one example: in many languages a sequence of two adjacent vowels is not allowed. Yet, it can happen that these languages do allow long vowels. One such language is Luganda (Rosenthall, 1994). In this language, it even is the case that, under the appropriate circumstances, a sequence of two vowels is changed into a long vowel. This unambiguously shows that long segments can be very different from a sequence of two

segments. The following illustrative examples are taken from Rosenthall (1994).

(6)

underlying structure	phonetic realization	
/ka+oto/	[ko:to]	'fireplace-DIM'
/ka+ezi/	[ke:zi]	'moon-DIM'

A way out of this dilemma was proposed in Clements and Keyser (1983). Inspired by McCarthy (1979), they propose that a long segment is a single segment linked to two positions on a timing tier. Schematically (and slightly simplifying) long segments have the following structure:

(7) long vowel long consonant

These representations can elegantly explain the hybrid nature of long segments. Their geminate character is expressed at the level of the timing units. At that level they occupy two positions. However, at the segmental level they are just one single element. This can explain why there are phenomena that do not treat long segments as geminates.

With the help of these representations, certain frequently occurring processes could easily be explained that were very puzzling from the perspective of the feature [long]. Some of the more important phenomena are compensatory lengthening, prenasal-consonant lengthening and postconsonant-glide lengthening. Compensatory lengthening is a process whereby a segment is lengthened if a neighboring segment is deleted (Hayes, 1989). The following example is from Turkish and it is taken from Sezer (1986).

(8) ovmak ~ o:mak 'rub, INF'

In terms of timing units, it is quite easy to understand what happens. The segment *v* is (optionally) deleted, but its timing unit is left behind. This is then filled by the vowel.

(9)

In prenasal-consonant lengthening, a nasal segment is moved from a closed syllable to the onset of the next syllable (Clements, 1986). Again, the moving segment leaves its timing unit behind. The vacated timing unit is then filled by the neighboring vowel. The following illustrative examples are from Luganda.

(10)

/ku + linda/	[kuli:^{n}da]	'to wait'
/ba + ntu/	[ba:^{n}tu]	'people'

At the level of the timing units, this change can be expressed in the following way:

(11)

Another frequent phenomenon involving timing units is postconsonant-glide lengthening. This is a process whereby a high vowel is moved to the onset, where it is realized as a glide. Again the vacated timing unit is filled by the neighboring vowel. The following examples are again from Luganda. They are taken from Clements (1986).

(12)

/li + ato/	[l^{y}a:to]	'boat'
/mu + oyo/	[m^{w}o:yo]	'soul'

In terms of the timing units, the following changes take place:

(13)

All these phenomena have in common that they cannot be explained with the feature [long]. In the case of postconsonant-glide lengthening, for instance, it is difficult to understand why a vowel is changed from [−long] to [+long] when the high vowel preceding it is syllabified in the onset position. There is no natural connection between the movement of the high vowel and the change from [−long] to [+long]. In terms of timing units, however, the connection is clear, as explained above: the moving segment leaves its timing unit behind.

The interest of processes such as compensatory lengthening, prenasal-consonant lengthening and postconsonant-glide lengthening can hardly be underestimated. Not only do they show that the feature [long] is highly problematic, they also provide independent motivation for the representation of quantity in terms of linking relations between two levels, the segmental level and the level where timing units are located.

This hypothesis has also served as an explanation for two important properties of geminate consonants, integrity and inalterability. Integrity refers to the fact that a geminate consonant typically does not allow epenthesis in between its two timing units. Guerssel (1978) shows that the Ait Segrouchen dialect of Berber (Middle Atlas Berber) has a rule that epenthesizes a schwa after the first consonant in a series of three consonants. However, this rule does not apply in a form such as /ddlu/ 'she covered,' showing that a geminate consonant blocks the rule.

Inalterability refers to the fact that many processes that apply to short segments do not apply

to corresponding geminate consonants. Tiberian Hebrew is a famous example of a language where geminate consonants exhibit inalterability effects. In this language, velars, labials, and nonemphatic consonants spirantize in postvocalic position (Elmedlaoui, 1993). However, spirantization does not apply to a geminate consonant. This is illustrated by the following examples (taken from Elmedlaoui, 1993):

(14)	Causative Perfect	Basic Perfect	
	[zik:e:r]	[za:xar]	'remember'
	[kip:e:r]	[ka:φar]	'cover'

Many explanations of integrity and inalterability have been based on the doubly linked representation of geminates. According to some proposals, integrity would follow from the fact that epenthesis in the domain of a geminate violates one of the fundamental principles of autosegmental phonology: association lines should not cross (Goldsmith, 1976). To see this, consider what would happen if a vowel were inserted in our Berber example /ddlu/ ('v' represents a vowel').

(15)

Epenthesis would necessarily have to break the lines connecting the segmental level of the geminate with the level of its timing units. Since this is not allowed, epenthesis is not possible (Goldsmith, 1990).

Inalterability has been explained by conditions governing the interaction between rules and representations (Hayes, 1986; Schein and Steriade, 1986). Recent theories, in particular Optimality Theory, can no longer work with these conditions, for the simple reason that they no longer recognize rules. Interestingly, it has been revealed in a number of publications that these rule conditions are empirically wrong anyway, because they make incorrect predictions as to the class of processes that exhibit inalterability (Inkelas and Cho, 1993; D. Churma, personal communication). According to Churma, inalterability only holds universally in the domain of lenition. This generalization cannot be captured by conditions on how rules interpret representations. Accordingly, researchers have sought to explain inalterability along entirely different lines. Kirchner (1998) proposes that the behavior of geminates with respect to lenition phenomena is to be understood in terms of avoidance of articulatory effort. Thus, geminate stops tend not to undergo lenition for the simple reason that lenited geminates, i.e., geminate continuant consonants, require more articulatory effort. Independent evidence for this hypothesis, according to Kirchner, comes from the crosslinguistic distribution of geminate consonants; languages with geminate obstruents overwhelmingly have geminate stops. That is, there are (almost) no languages with geminates fricatives without the corresponding geminate stops (Kirchner admits that there are two exceptions in Maddieson, 1984: Greenlandic and Iraqw). It should be noted that in Kirchner's explanation, the geminate representation of long consonants does not play a crucial role; long consonants could just as well be represented as [+long].

Two further problems concerning geminate segments should be mentioned. The first concerns the phonetic interpretation of doubly linked segments. According to some researchers, it is not always the case that phonological geminates are realized phonetically as long segments. Thus, Ségéral and Scheer (2001) show quite convincingly that in Somali certain consonants behave as if they are geminates, although they are phonetically short. The 'ambisyllabic' consonants of Dutch provide another argument for the hypothesis that phonological geminates are not necessarily phonetically long segments.

In Dutch closed, penult syllables normally attract stress (van der Hulst, 1984). Interestingly, words with a lax vowel in the penult syllable also attract stress, as shown by a word such as *gorílla*. Both phenomena find a uniform explanation if it is assumed that in words such as *gorílla* the intervocalic *l* is really a geminate, as suggested by Dutch orthography. But that is only possible if we are willing to accept that phonological geminates are not always phonetically long, because in Dutch the consonants in intervocalic position following a lax vowel are definitely short. If we admit this possibility, then we have the following relation between phonetically long segments and phonologically geminate segments. While it is presumably true that phonetically long segments always have a geminate representation in phonology, the reverse does not hold; phonologically geminate segments are not always phonetically long.

There is another problem that still has not been solved. It was soon discovered that there is something fundamentally wrong with timing units. To understand why timing units are problematic we have to consider compensatory lengthening again. We have seen that in Turkish in a word such as *ovmak* the *v* can optionally be deleted and that this deletion process is accompanied by the lengthening of the preceding vowel. Interestingly, deletion is not always accompanied by vowel lengthening. In a word like *ovar* 'rub, AOR,' for instance, the *v* can be deleted, but if that happens the preceding vowel is not lengthened. How can words such as *ovmak* be distinguished from words such as *ovar*, such that consonant

deletion leads to vowel lengthening only in the former type? In terms of timing units, the answer is not obvious. In fact, there is no reason why the vowel should not lengthen after the deletion of the consonant in a word such as *ovar*. This is shown in the following representation.

(16)

Hayes (1989) tried to solve this problem with the help of moraic structure. According to Hayes, segments that trigger vowel lengthening after deletion are associated with a mora, whereas the consonants that are not accompanied by vowel lengthening after deletion are not linked to a mora. In this theory, the two Turkish examples can be distinguished as follows (the status of the word-final consonant in terms of moraic structure has not been made explicit):

(17)

In *ovmak* the *v* is linked to a mora. If it is deleted its mora is left behind. This mora can be the target for the vowel. In *ovar*, on the other hand, nothing is left behind if the consonant is deleted, so there is no target for the vowel. This is shown in the following representations.

(18)

One of the major predictions of this theory is that the loss of onset consonants can never be accompanied by lengthening, because onset consonants are never moraic.

With the replacement of timing units by moras, geminate vowels can be represented straightforwardly as one segment linked to two moras, as shown in the representation of *[o:mak]*. Now, the problem that still has not been solved concerns the representation of geminate consonants in terms of moraic structure.

One possibility would be to say that geminate consonants have a mora. In this view gemination of consonants is expressed in terms of double linking between a single segment and a mora plus an adjacent syllable (at least in most cases). Interestingly, this representation explains many integrity and inalterability effects, as shown in Inkelas and Cho (1993). In their analysis, these effects are a consequence of the fact that phonological processes do not apply to geminate consonants, because, if they would, they would lead to the loss of a mora. This is not allowed.

In the moraic theory of geminate consonants, the Latin word *mitella* (cf. above) would have the following representation.

(19)

This theory, proposed in Hayes (1989), predicts that geminate consonants **always** contribute to weight, because weight is expressed in terms of moraic structure. According to many phonologists, this is highly problematic. Languages do exist where geminate consonants do not contribute to weight (Selkirk, 1990; Tranel, 1991; Baker, 1997; Hume *et al.*, 1997). The argument presented by Hume *et al.* is particularly revealing. They show that Leti has a minimal word condition that requires lexical words to be minimally bimoraic. Leti also has geminate consonants in word-initial position. Now, if geminates were moraic, then it is predicted that Leti has words of the forms [c:v], because these words would satisfy the minimal word condition. In fact, Leti does not have these words. This is a problem for the moraic theory of geminates, according to the authors. To solve this problem, they propose to express gemination in terms of root nodes; a geminate consonant is a segment with two root nodes.

(20)

The first root node may or may not be linked to a mora. This is determined on a language-particular basis. In Latin it is, which explains why in this language geminates attract stress. In Leti it is not, according to Hume *et al.* (1997) The latter assumption explains why Leti does not have words of the structure [c:v]. These words do not satisfy the minimal word condition, because in this language geminates do not have a mora. This can be shown with the following representation.

(21)

Davis (2003) proposes an alternative solution, allowing him to maintain the moraic theory of geminates. He suggests that the initial geminates of Leti are extraprosodic. He shows that this is independently motivated by the phonotactics of this language. In word-initial position, Leti allows for almost any possible sequence of two consonants. There are no sonority restrictions on this sequence. This indicates that Leti has an extraprosodic position at the beginning of a lexical word. The structure of geminate consonants is an aspect of phonological quantity that is still not entirely clear.

Quechua

W F H Adelaar, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The name Quechua (also Quichua or Runa Simi) is used for a group of closely related Amerindian languages or dialects, spoken in parts of the Andean states of Argentina, Bolivia, Colombia, Ecuador, and Peru. Although Quechua is traditionally referred to as a language and its local varieties as dialects, substantial local differences often prevent mutual intelligibility. Estimates for the total number of Quechua speakers vary between 7 and 10 million, although the lower number seems to have a firmer statistical basis. In Peru, the number of Quechua speakers ranges between 3 and 4 million; in Bolivia there are about 2 400 000 speakers. Geographically, the Quechua language area does not form a continuum; it is interrupted by large hispanophone and Aymara-speaking regions.

Linguistic reconstruction suggests that, at the end of the first millennium A.D., Quechua was widely spoken along the coast and in the mountains of central Peru with possible extensions into the southern and northern Andean parts of that country. Toward the end of their expansion, at the end of the 15th century, the rulers of the Inca empire adopted as their language of administration a variety of Quechua, referred to by the Spanish conquerors as *La lengua general del Inga* ('The general language of the Inca'). The Incas contributed to the spread of Quechua into outlying areas of their empire (highland Ecuador, northwestern Argentina) by an active policy of forced migrations (*mitimaes*).

The name Quechua came into use in the second half of the 16th century. It was probably derived from the term for temperate altitude zones situated at about 10 000 feet or from the name of a province and ethnic group in the present-day department of Apurimac. The first grammar of Quechua, by Domingo de Santo Tomás, dates from 1560. During most of the colonial period, the Spanish authorities stimulated the use of Quechua as a language of colonization and evangelization, introducing it to the detriment of many local languages into areas where it had never been used before. A new standard language was created, soon to be replaced as the language of indigenous prestige by the Quechua dialect of the former Inca capital Cuzco. The early 18th century brought a period of Quechua cultural revival and literary activity. It came to an end around 1770, when cultural and linguistic repression by the Spanish rulers initiated the decline of the Quechua language that has continued until recently. In spite of stimulating measures, such as the official recognition of Quechua as a second national language in Peru (1975), the prospects of Quechua have hardly improved.

From a historical and genealogical point of view, Quechua has no proven external relatives. There are phonological, structural, and lexical similarities with the neighboring Aymaran (also called Jaqi or Aru) languages, which indicate a protracted period of interaction between the two groups. Most of these similarities, which also include more than 20% of shared lexicon, do not extend to other languages in the area. The similarities between Quechua and Aymaran have often been interpreted as proof of a common origin (the Quechumaran hypothesis). However, practically all the similarities can be attributed to convergence, making it difficult to distinguish between borrowed and inherited material (*see* **Aymara** and **Andean Languages**).

Internally, the Quechua family is subdivided into two main groups. The first group (Quechua I or Central Peruvian Quechua) is located in the Andes of central and central northern Peru. One of its most

Quechua

W F H Adelaar, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The name Quechua (also Quichua or Runa Simi) is used for a group of closely related Amerindian languages or dialects, spoken in parts of the Andean states of Argentina, Bolivia, Colombia, Ecuador, and Peru. Although Quechua is traditionally referred to as a language and its local varieties as dialects, substantial local differences often prevent mutual intelligibility. Estimates for the total number of Quechua speakers vary between 7 and 10 million, although the lower number seems to have a firmer statistical basis. In Peru, the number of Quechua speakers ranges between 3 and 4 million; in Bolivia there are about 2 400 000 speakers. Geographically, the Quechua language area does not form a continuum; it is interrupted by large hispanophone and Aymara-speaking regions.

Linguistic reconstruction suggests that, at the end of the first millennium A.D., Quechua was widely spoken along the coast and in the mountains of central Peru with possible extensions into the southern and northern Andean parts of that country. Toward the end of their expansion, at the end of the 15th century, the rulers of the Inca empire adopted as their language of administration a variety of Quechua, referred to by the Spanish conquerors as *La lengua general del Inga* ('The general language of the Inca'). The Incas contributed to the spread of Quechua into outlying areas of their empire (highland Ecuador, northwestern Argentina) by an active policy of forced migrations (*mitimaes*).

The name Quechua came into use in the second half of the 16th century. It was probably derived from the term for temperate altitude zones situated at about 10 000 feet or from the name of a province and ethnic group in the present-day department of Apurimac. The first grammar of Quechua, by Domingo de Santo Tomás, dates from 1560. During most of the colonial period, the Spanish authorities stimulated the use of Quechua as a language of colonization and evangelization, introducing it to the detriment of many local languages into areas where it had never been used before. A new standard language was created, soon to be replaced as the language of indigenous prestige by the Quechua dialect of the former Inca capital Cuzco. The early 18th century brought a period of Quechua cultural revival and literary activity. It came to an end around 1770, when cultural and linguistic repression by the Spanish rulers initiated the decline of the Quechua language that has continued until recently. In spite of stimulating measures, such as the official recognition of Quechua as a second national language in Peru (1975), the prospects of Quechua have hardly improved.

From a historical and genealogical point of view, Quechua has no proven external relatives. There are phonological, structural, and lexical similarities with the neighboring Aymaran (also called Jaqi or Aru) languages, which indicate a protracted period of interaction between the two groups. Most of these similarities, which also include more than 20% of shared lexicon, do not extend to other languages in the area. The similarities between Quechua and Aymaran have often been interpreted as proof of a common origin (the Quechumaran hypothesis). However, practically all the similarities can be attributed to convergence, making it difficult to distinguish between borrowed and inherited material (*see* **Aymara** and **Andean Languages**).

Internally, the Quechua family is subdivided into two main groups. The first group (Quechua I or Central Peruvian Quechua) is located in the Andes of central and central northern Peru. One of its most

vital dialects is Ancash Quechua, but many other Quechua I dialects are close to extinction. The second group (Quechua II) comprises the dialects spoken in southern Peru (Ayacucho, Cuzco, Puno), some dialects in northern Peru (Cajamarca, Ferreñafe, Chachapoyas, Lamas), and all the Quechua dialects spoken in Bolivia (Apolo, Cochabamba, Potosí, Sucre), Ecuador (Highland and Eastern Lowlands Quichua), Argentina (Santiago del Estero, Jujuy), and Colombia (the Ingano dialect in Caquetá and Nariño). The largest numbers of Quechua speakers use the Ayacucho, Cuzco, and Puno dialects; Bolivian Quechua; and Ecuadorian Highland Quechua.

Quechua phonology varies according to dialect, but is generally simple. The vowel system consists of three vowels (*a*, *i*, *u*), the high vowels being lowered to (*e*, *o*) next to a uvular consonant. An additional distinction between long and short vowels is found in Quechua I. Stops are generally voiceless. There is a contrast between velar and uvular stops, although the latter have become fricative in many dialects. Some dialects preserve a distinction between palatal and retroflex affricates. Glottalized and aspirated stops are found in the dialects bordering on Aymara (Cuzco, Puno, Bolivian); aspirated stops are also found in Ecuador. In most dialects, stress is predictably located on the penultimate syllable or mora. Quechua word structure does not allow sequences of consonants within a syllable.

Quechua has an agglutinating structure mainly based on suffixation; there are no prefixes at all. The morphology is complex, but regular. (Ecuadorian and Colombian Quechua have a much simplified morphology in relation to the other Quechua dialects.) Words containing as many as eight consecutive suffixes are not exceptional. Verb-final order is obligatory in dependent clauses, and it is the preferred constituent order in full sentences. In noun phrases, all modifiers precede their heads, except for relative clauses in some dialects.

Nouns can be marked for case, number (plural), and person of possessor. The overall structure of the language is nominative-accusative. Objects must be marked for accusative case, unless they precede a nominalized verb. Plural marking on nouns is optional, although not infrequent. In the southern Quechua II dialects, both the number of a nominal referent and of its possessor can be indicated morphologically. The pronominal system and the personal paradigm include a distinction between inclusive and exclusive first-person plural.

Verbs in Quechua exhibit a rich derivational morphology, including causative, applicative, reflexive, reciprocal, desiderative, and several other options; they are also marked for tense, mood, aspect, speaker orientation ('hither'), personal reference (including the inclusive-exclusive distinction), and number (of subject and/or object). Personal reference not only includes a specification of the subject but also of a direct or indirect object, provided that the latter is a participant in the speech act. In the area of personal reference, tense, and mood, several portmanteau suffixes occur.

Nominalization and direct verbal subordination play a central role in Quechua morphosyntax. Different types of dependent clauses are obtained by combining nominalized verbs with specific case markers. Nominalization is also used to form relative clauses. Subordinated verbs encode a system of switch-reference (i.e., they indicate whether or not the subject of the dependent clause coincides with that of the main clause).

Sentential affixes or enclitics are used to indicate evidentiality (assertion, hearsay, conjecture), topic-comment structure, interrogation and negation, inclusion ('also'), (non-)completion ('already,' 'yet'), emphasis, and several attitudinal functions.

Queer Language and Queer Linguistics

The word 'queer' has been used in a variety of ways (see McConnell-Ginet (2002) for a detailed discussion). In the early 20th century in the United States, the term queer was used as a term of self-reference (or identity category) for homosexual men who adopted masculine behavior (Chauncey, 1994: 16–18). By the 1970s, 'queer' had been appropriated by heterosexuals as a pejorative and ceased to be used as a term for self-reference by homosexual men. In the late 1980s and early 1990s, a political activist organization known as Queer Nation attempted to reclaim 'queer' as a general term for sexual and gender minorities. The term was subsequently taken up in academic writing in the emerging field of queer theory, an extension of theoretical work in feminist theory that deals with issues of sexuality, sexual identity, and gender identity. The term queer has since been used in different and often conflicting ways. As originally used in queer theory, the term queer was not intended as an identity label to refer to a particular externally defined group. Queer theorists rejected terms such as 'gay' or 'lesbian' as inherently exclusionary and argued that identity categories marginalize individuals who are not prototypical members of a given identity category. The use of 'queer' was intended as a means of rejecting identity labels by proposing a term that referred to all individuals who were marginalized in some way by heteronormativity, the social norms associated with hegemonic heterosexuality. Thus, 'queer' includes (but is not restricted to) all sexual and gender minorities. In this usage, the actual membership in a 'queer' community is left intentionally vague because 'queer' is defined not in terms of who belongs but in terms of what queers react against. Thus, the common denominator for queers is their marginalization and exclusion rather than being unified by some common identity or shared social practices. The 'queering' of academic disciplines was proposed as a means of turning attention toward those individuals who had been traditionally marginalized in social theory. By focusing on individuals who are not prototypical members of traditional (etic) identity categories, queer theory attempts to gain insight into the normative forces that underlie social practice. Research that falls within the realm of queer linguistics does not always deal with speakers who are gay, lesbian, or transgendered but may deal with speakers who are marginalized in other ways, as with Mary Bucholtz's (1999) research on the language of self-proclaimed 'nerds.'

Within linguistics, this use of 'queer' has been adopted by those working in 'queer linguistics' (Barrett, 1997, 2002; Bucholtz and Hall, 2003, 2004; Hall, 2003; Livia and Hall, 1997a) in an attempt to adopt and amend proposals from queer theory into a framework for the study of language. Although 'queer' within queer linguistics was intended to refer to queer theory (rather than any community of actual queers), this use of 'queer' has been criticized primarily on the grounds that it does not refer to any externally definable social group (Kulick, 2000; Leap, 2002). In contrast to sociolinguistic frameworks focusing on norms of language variation that categorize individuals into speech communities based on etic identity categories, queer linguistics assumes that speech communities are prototype categories that do not have clearly definable boundaries. The field of queer linguistics emphasizes the language practices at the margins of traditional approaches in order to examine how membership in particular speech communities is negotiated and contested (Bucholtz and Hall, 2003, 2004). Central to queer linguistics is the view that the indexical meanings associated with linguistic variables are performative in that they may create both speaker identities and social contexts. By using particular linguistic variables, speakers may associate themselves with (or in opposition to) particular identity categories and norms for the interpretation and use of indexical meanings (Bucholtz and Hall, 2003, 2004) (*see* **Pragmatic Indexing**).

In usage outside of academic writing, the term queer is often used as a cover term to refer to gay, lesbian, bisexual, and transgendered people. However, recent usage suggests that in public discourse 'queer' may be shifting toward use as an androcentric generic, similar to 'man' or 'gay' (Cohen, 2002). Rather than attempt to discuss the language of a hypothetical group of queers, the remainder of this article focuses on studies that have been central in the development of queer linguistics, including gay and lesbian language use, transgendered language, and the role of language in maintaining heteronormativity.

The Study of Gay Male and Lesbian Language

The study of gay male ways of speaking first emerged in the early 20th century (see Cameron and Kulick (2003) for a summary of the history of this research). During this period, male homosexuality was understood largely in terms of gender expression, and men

and women who displayed normative gendered behaviors were not generally considered homosexual, even if they engaged in sexual acts with members of their own sex (Chauncey, 1994). Early work typically viewed homosexuality as a psychological disorder and usually involved collecting lexical items from the 'secret' argot of homosexual men. Because gay male language was seen as a byproduct of deviant sexuality and gender expression, research focused primarily on sexual vocabulary and the alternative use of gendered language, such as the use of female pronouns and feminine proper names by gay men. During this period, the language of lesbians received much less attention, given the centrality of effeminate men in prevalent understandings of homosexuality.

In the years before and after World War II, views of homosexuality shifted so that 'gay' identity was understood in terms of sexual practices rather than gender expression. It was during this period of research that current debates about gay and lesbian language began to emerge. Whereas some linguists saw gay male and lesbian language as a unique form of cultural expression, others viewed gay and lesbian 'argot' as a result of oppression and marginalization. Those who favored assimilation and believed that gay men and lesbians should differ from heterosexuals only in terms of sexual practice viewed homosexual 'slang' as a byproduct of oppression against homosexuality.

After the Stonewall riots in New York in 1968 and the passage of the 1967 Sexual Offences Act in the United Kingdom, the gay and lesbian civil rights movement began to gain ground. During the 1970s, research on gay male language continued to focus primarily on lexical items and gender crossing. Building on the 'ethnic model' of the civil rights movement, linguists typically viewed gay male language as a basic component of gay and lesbian culture. During this period, scholars such as Bruce Rogers (1972) and Julia Penelope Stanley (1970) collected extensive vocabularies of lexical items that were typically seen as reflecting the unique cultural identity of gay and lesbian speakers. Some scholars, however, continued to view gay and lesbian language as a secretive argot (Farrell, 1972).

The first major collection of research specifically examining gay and lesbian language was *Gayspeak* (Chesebro, 1981). This collection laid out many of the debates that had been building in the field and continue into more recent research (Barrett, 2003). Hayes (1981) argued that 'gayspeak' was an authentically gay way of speaking that differed from heterosexual language in three particular contexts: the 'secret setting,' the 'social setting,' and the 'activist-radical setting.' In the secret setting gay men use particular forms of language to convey their sexuality to one another without making their sexuality known to heterosexuals who might hear their conversation. Painter (1981) also described this type of covert communication among lesbians. In the social settings, Hayes described the use of specific vocabulary and discourse styles associated with contexts in which all participants were gay, whereas the activist–radical setting referred to the language of the gay and lesbian civil rights movement. In responding to Hayes, Darsey (1981) questioned the existence of gayspeak, arguing that the structures described by Hayes were not unique to gay or lesbian communities. Like earlier scholars who believed that the unique elements of gay language resulted from resistance to social stigma, Darsey argued that gay male language was not particularly different from the language used by other marginalized groups.

The debate between Darsey and Hayes resurfaced in response to the work of William Leap (1996). Leap followed Hayes in arguing for an authentically gay male language, gay men's English, that differs from the language of heterosexuals. Leap described gay men's English largely in terms of norms for interaction such as the use of cooperative discourse. Kulick (2000) followed Darsey in claiming that none of the structures described by Leap are unique to gay men and, therefore, gay men's English does not exist. However, Leap openly admitted that his view of gay men's English is restricted to a specific subset of gay men, namely white middle-class men in the United States. Leap argued that although gay men's English does not reflect the language of all gay men who speak English, it is an important marker of gay identity for many speakers and has spread to other groups of gay men with the globalization of Western views of homosexuality (Leap and Boellstorff, 2004).

Work in queer linguistics proposes an alternative to this argument (Barrett, 1997; Queen, 1997), arguing that although the linguistic structures of gay and lesbian language overlap with the speech of other social groups, it is more likely that the distinctive character of gay and lesbian language might be found in the ways in which those structures are combined (instead of the structures themselves). For example, Harvey (1998, 2000) analyzed what he called 'camp talk' as a set of rhetorical devices that produce a style that indexes gay male identity. Harvey argued that camp talk involves four basic linguistic strategies: paradox (the juxtaposition of contradictory or conflicting meanings), inversion (the reversal of the expected meanings of signs, such as the use of 'she' to refer to a man), ludicrism (utterances that highlight ambiguity or indeterminacy in meaning), and parody (forms that exaggerate stereotypes about speaker

orientation). In Harvey's analysis, the linguistic structures involved are not uniquely gay, but the way in which particular structures are combined serves to index gay male identity.

Structural Aspects of Gay Male and Lesbian Language

Although current views of homosexuality distinguish gender expression from sexual orientation, stereotypes of gendered language use continue to play an important role in the perception of speech as 'gay' or 'straight.' Several studies have examined the linguistic features stereotypically associated with gay male or lesbian speech (see Jacobs (1996) for a review). Although some of this research suggests that these features may be used by listeners in perceiving speech as gay or straight, researchers have found no direct correlation between these forms and actual use by those who identify as gay or lesbian. The phonetic aspects of speech that are stereotypically perceived as 'gay male' in English include hyperstandard pronunciation, such as longer duration of sibilant fricatives and /l/ (Crist, 1997), a longer voice onset time for voiceless aspirated stops, and the release of word-final stops (Podesva *et al*., 2002). Also, a wider intonational pitch range is often associated with stereotypical gay-sounding speech (Gaudio, 1994; Smyth *et al*., 2003). In contrast, stereotypes of lesbian speech include a narrow pitch range and 'flat' intonation patterns (Moonwomon, 1997; Queen, 1997).

These stereotypes of gay male and lesbian speech often reflect stereotypes of gendered language use. This is the case, for example, with syntactic and lexical variation. Gay male speech is often viewed as having hyperstandard speech and using lexical items stereotypically associated with women, whereas lesbian speech is often associated with male stereotypes, such as nonstandard or working-class speech and the use of obscenities. Although these features do no reflect actual usage by gay men and lesbians, speakers may use these linguistic stereotypes to convey sexual orientation in specific contexts. Livia (1995), for example, demonstrated how literary representations of lesbians rely on stereotypes of 'men's language,' including limited responses, avoiding expressions of emotion, and the use of sexually explicit vocabulary. A number of research questions remain largely unexplored, including a more detailed understanding of when and how these stereotypes are exploited by gay men and lesbians, whether or not (and how) they might be used by speakers who identify as bisexual, and the various indexical meanings listeners associate with specific variables that have been associated with stereotypes of sexual orientation.

Gay and Lesbian Lexicons

Most early studies of gay male and lesbian language use focused on 'homosexual slang,' or the lexical items unique to gay and lesbian communities. A number of researchers have published lexicons of terms used in gay and lesbian communities (Baker, 2002a; Cory, 1965; Legman, 1941; Stanley, 1970; Rodgers, 1972). Many early researchers viewed gay and lesbian vocabulary as a mechanism for dealing with the stigma of homosexuality. Some viewed gay/lesbian slang in a positive light, holding that unique vocabulary was a survival strategy creating a social space in which being homosexual was acceptable. Others viewed the gay/lesbian vocabulary as a negative result of social marginalization that continued to exclude gay men and lesbians from larger society, whereas others argued that gay vocabulary was not simply a mechanism for dealing with stigma but that it was a means of defining social roles in gay and lesbian communities (Kulick, 2000). As is common in research on homosexual language, these studies typically gave comparatively little attention to lesbian vocabulary.

The most well-known and structurally distinct gay male language variety was Polari (Baker, 2002b) used in the United Kingdom. Polari evolved from a variety of sources, including Lingua Franca as used by English sailors, the language of those working in the entertainment industry, Cockney rhyming slang, and the language of prostitutes. Although Polari contains some unique syntactic patterns (Baker, 2002b: 52–56), the primary difference between Polari and other varieties of English is the use of a unique vocabulary. The vocabulary of Polari, however, is unique among gay/lesbian varieties in that it is so extensive as to be unintelligible to the majority of English speakers, as in the following example (Baker, 2002b: 53):

Polari:	varda the naff hommie with nante pots in the cupboard
Translation:	look at this unsightly wretch with the appalling dentistry

Use of Polari has declined dramatically since the 1960s. The lack of knowledge of Polari among younger speakers leads Baker (2002b: 109–111) to conclude that Polari is a dying language.

The decline of Polari is related to the shift in understandings of homosexual identity from being based primarily on difference in gendered behavior to being based on sexual attraction and behavior. The culmination of this shift in the gay and lesbian civil rights movement led to a period in which gay male identity was typically conveyed through behaviors that reflected a unique form of masculinity rather than

through stereotypical 'feminine' behavior (Levine, 1998). The backlash against camp or feminine behavior during the 1970s and early 1980s led to a similar decline in the use of many gay male lexical items in the United States. The rejection of in-group language that was viewed as feminine did not, however, end the use of in-group forms of communication but led to the formation of new systems of in-group communication. For example, in the 1970s the 'hanky codes' emerged in the 'clone' community in the United States. The hanky codes involved the use of colored bandanas in one's back pocket as a way of signaling preferences for particular sexual acts. For example, light blue signified a preference for oral sex, whereas dark blue signified anal sex. Bandanas worn on the left side indicated a preference for being the active partner (or 'top'), whereas those worn on the right side indicated a preference for being the passive partner ('bottom') (Levine, 1998: 65–66).

Gay Male and Lesbian Discourse

Given that grammatical features associated with gay and lesbian language seem to be related to stereotypes rather than actual usage, a number of linguists have focused on gay and/or lesbian norms for structuring discourse and conversational interaction instead of the use of particular linguistic structures (McIlvenny, 2002). Studies of both gay male and lesbian discourse have tended to focus on the collaborative nature of gay and lesbian interaction. Although collaborative discourse is certainly not unique to gay or lesbian speakers (*see* **Cooperative Principle**), some linguists have argued that gay men and lesbians use cooperative norms for interaction as a means of asserting a shared identity based on sexual orientation. The most distinctive aspect of this cooperative discourse is the assumption of shared cultural knowledge associated with sexual orientation. Studies have highlighted the role of cooperative discourse in the affirmation of both gay male (Leap, 1996) and lesbian (Morgan and Wood, 1995) identity as well as the role of cooperative discourse in asserting shared identity between gay men and lesbians (Queen, 1998a, 1998b). In a detailed study of crosssex conversation between gay men and lesbians, Queen (1998b) found that although speakers used language to form a unified identity as homosexuals based on shared cultural knowledge, gay men and lesbians also used structures stereotypically associated with gendered conversational styles. Although an assumption of shared cultural knowledge may be important in particular contexts, it is not the case that all gay or lesbian interactions are necessarily 'cooperative.' For example, several studies have examined the genre of verbal dueling and the use of ritual insults among gay men (Goodwin, 1989; Murray, 1979; Read, 1980).

Another aspect of gay and lesbian discourse that has received a great deal of attention is the ways in which gay men and lesbians convey sexual orientation to one another through the use of conversational implicature (*see* **Implicature**) (Hayes, 1981; Leap, 1996; Liang, 1999; Painter, 1981). As with cooperative discourse, this use of implicature is not uniquely gay or lesbian but relies on the assumption of shared knowledge of gay or lesbian cultural norms as a means of conveying sexual identity. Speakers may use implicature to convey homosexual orientation such that the actual meaning ('I am gay/lesbian') can only be inferred if the listener has some prior knowledge of gay/lesbian culture. Such a use of implicature allows gay and lesbian speakers to reveal their sexual orientation to one another without necessarily revealing themselves to heterosexuals involved in the same conversation. A speaker might, for example, respond to a question about how one spends his or her free time by referring to spending time in a particular neighborhood with the understanding that only other gay men or lesbians will recognize that neighborhood as a center of gay/lesbian culture. Similarly, before the use of the term 'gay' became widely recognized as meaning homosexual, men might have used the word to convey their sexual orientation to one another with the assumption that heterosexual listeners would not likely understand that the word referred to sexual orientation, as in the following example from Hayes (1981: 46):

> Mr. X: You certainly have a colorful tie.
> Mr. Y: Yes, I really like gay apparel.

Another aspect of gay and lesbian discourse is the use of particular verbal genres such as ritual insults or verbal dueling. The most widely studied genre associated with gay and lesbian speakers is the 'coming out story.' 'Coming out (of the closet)' refers to the act of revealing one's homosexual identity. There are competing notions of what exactly it means to be 'out' (i.e., openly homosexual), and one may be 'out' in particular social contexts and 'not out' in others (Zwicky, 1997). Studies of coming out stories in a variety of local communities have found strikingly similar structure in the genre (Liang, 1997; Maher and Pusch, 1995; Wood, 1997, 1999). Coming out narratives typically include the following stages (Liang, 1997):

1. Recognition of the processual nature of coming out
2. Coming out to self
3. Coming out to other

As with concepts such as cooperative discourse or the use of implicature to convey sexual identity, the coming out story is founded on assumptions of shared knowledge of gay and lesbian cultural norms. One common feature of studies of gay and lesbian discourse is the critical role of a shared sexual identity in establishing cultural norms for language use.

Transgendered Language

The term 'transgender' is an umbrella term for individuals who display behavior patterns typically associated with the opposite sex, including transsexuals, drag queens/kings, and transvestites. Transsexuals are those who believe that the sex they have been assigned based on physical appearance does not correspond to their psychological and social experience. Some transsexuals undergo sex-reassignment surgery to repair the dichotomy identity vs. biology. In terms of language, transsexuals typically attempt to adjust their speech patterns to reflect normative expectations of gendered use of language. For male-to-female (MTF) transsexuals, language is a central component in changing one's gender identity. MTF transsexuals typically adopt stereotypes of gendered language use and may undergo speech therapy in order to sound more feminine. The move toward stereotyped 'women's language' typically involves raising the pitch of one's voice, using a wider range of intonation patterns, speaking more softly, and using lexical items stereotypically associated with women's language. Although research on MTF transsexuals almost always includes a linguistic component, the language of FTM (female-to-male) transsexuals receives very little attention. This is often explained by the fact that the testosterone taken by FTM transsexuals thickens the vocal chords, lowering a speaker's pitch. Thus, it is often assumed that learning to speak 'like a man' is not a problem for FTM transsexuals. However, the lack of attention given to FTM speech is also tied to an ideology in which men's language is unmarked with respect to women's language (Kulick, 1999).

Although the language of transsexuals is typically seen as reproducing stereotypes of gendered language, other forms of transgendered language seem to center around undermining these stereotypes. Drag queens (gay men who dress in women's clothing) often use stereotyped women's language, but often mix stereotypically masculine forms into their feminine speech. African–American drag queens, for example (Barrett, 1998, 1999), typically juxtapose linguistic forms that stereotypically index identities that are in opposition. For example, a speaker may use stereotyped feminine 'ladylike' speech mixed with obscenities or juxtapose language that indexes a white middle-class identity with forms from African–American English. Although the use of feminine speech for MTF transsexuals is an attempt to change general speech patterns in all situations throughout one's life, the use of feminine speech for drag queens is temporary and highly dependent on social context.

Descriptions of linguistic forms that index a speaker's gender have noted transgendered speech in a variety of languages. A number of Native American languages contain grammatical elements described as corresponding to the gender of a speaker. Most of the descriptions note that there are 'exceptional' speakers who sometimes use the forms corresponding to the opposite gender (Hall, 2003). Detailed research on Lakhota (Trechter, 1999) suggests that use of gender-marked elements by members of the opposite sex does not simply convey a transgendered identity. Rather, the meaning of gendered elements is highly dependent on context and may convey personal attributes other than gender. Hall and O'Donovan (1996) also found that Hindi-speaking *hijras* use grammatical gender marking to convey a variety of indexical meanings. Whereas hijras generally use forms marked as feminine for self-reference, they use masculine forms when foregrounding positive personal attributes associated with masculinity (e.g., owning a home or being trustworthy). Rudes and Healey's (1979) study of the uses of 'he' and 'she' by gay men in the United States also found that gendered pronouns were associated with particular indexical meanings. Although 'she' was used in positive references to physical attractiveness, most uses of 'she' were associated with negative attitudes toward the referent.

An important insight of this research has been the confirmation that the indexical meanings associated with gender are indirect (Ochs, 1992). Even in languages in which particular linguistic structures have been assumed to be direct markers of speaker gender (e.g., Lakhota or Hindi), these structures do not necessarily directly refer to speaker (or referent) gender. Rather, the structures associated with gender index particular social attributes, stances, or personality traits that are in turn associated with cultural assumptions about the particular attributes that are associated with masculine or feminine behavior. For example, Eckert (2002) noted that in American English, the release of word-final stops has been associated not only with the speech of gay men (Podesva *et al.*, 2002) but also with indexing 'Jewish speech' and the identity of female nerds. Rather than directly marking a given sexual identity or gender, released final stops seem to index something like "articulateness" (Eckert, 2002: 102). The relationship between indexical meanings and social categories is not direct,

but it is negotiated through indexing attributes that may in turn be associated with social categories.

Language and Heteronormativity

A final aspect of queer language is the role of language in maintaining heteronormativity, or the social norms that enforce hegemonic (compulsory) heterosexuality and marginalize gay, lesbian, or transgendered speakers. Although there is no *a priori* reason to assume that there is any relationship between norms for gendered behavior and sexual orientation, it is clear that speakers (and often researchers) assume some relationship between gender and sexuality. This research has transformed the field of language and gender (*see* **Gender and Language**) into the field of language, gender, and sexuality (Bucholtz, 2004). Speakers may refer to sexual orientation as a means of performatively asserting gender identity and vice versa (*see* **Heterosexism and/in Language**).

Cameron (1997) examined the way in which a group of heterosexual male college students use references to homosexuality to convey masculine gender identity. Cameron examined a conversation in which the men discuss 'gay' classmates at length. The most important aspect of Cameron's analysis is the fact that some of the 'gay' classmates are clearly heterosexual (one is described as constantly "hitting on girls"). The men are able to assert a masculine identity by distinguishing themselves from a classmate who they depict as homosexual (and hence effeminate). The actual sexual desires of the 'gay' classmates have little relevance to the interaction, and the discussion of sexual orientation is primarily used to construct masculine gender identity. Cameron's study demonstrates that linguistic references to sexual identity may be entirely divorced from actual sexual desires or sexual practices (Bucholtz and Hall, 2004).

Studies have also examined the reverse phenomenon, in which gender identity is used as a means of asserting sexual identity. Peebles (2004) examined the language in an ex-gay ministry in the United States. Ex-gays are evangelical Christians who have (or continue to) experienced same-sex attraction (and may have identified as gay or lesbian) but who attempt to transform their sexual identity to that of heterosexuals based on their religious belief that homosexuality is morally wrong. The transformation to a heterosexual identity revolves around negotiating and acquiring new norms for gendered behavior. The ex-gays in Peebles's study view the transformation as one of adopting some aspects of traditional normative gender behavior while questioning other aspects of stereotypical masculine or feminine behavioral norms (including norms for language use). Peebles's research demonstrated the inverse of Cameron's study, showing that sexual identity may be expressed through markers of gender identity.

Conclusion

The field of language and sexuality is a very recent phenomenon and its emergence has involved much debate (Bucholtz and Hall, 2004; Campbell-Kibler *et al.*, 2002). The focus on marginalized speakers in queer linguistics has resulted in new perspectives on the ways in which speaker identities are conveyed through language. In particular, the assumption that there are 'gender-exclusive' forms of language (i.e., structures used only by males or only by females) is no longer tenable given this attention to speakers who have generally been classified as 'exceptions' (Hall, 2003). However, much additional research is needed before we can begin to fully understand the relationship between language and sexual and gender identities.

Question Answering from Text, Automatic

U Hermjakob, USC Information Sciences Institute, Marina del Rey, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Question answering (QA) is a natural language processing application (*see* **Natural Language Processing: Overview**) in which, given a question in plain natural language and a document collection, the computer system delivers an exact answer (i.e., without spurious text) to that question based on the document collection. The following examples are illustrative:

Question: How many people live in Los Angeles?
Answer: 3 912 200
Question: Who was Bach?
Answer 1: Johann Sebastian Bach, German baroque composer and organist, 1685–1750. One of the greatest . . .
Answer 2: Carl Philipp Emanuel Bach . . .
⋮
Answer 6: Edward Bach, British medical microbiologist, 1880–1936 . . .

General QA systems are open domain, i.e., there are no restrictions on the question type or topic. Answers can range from simple entities, such as names and quantities, to highly structured responses. Practical systems typically provide a ranked list of answers with some form of justification, e.g., with relevant extracts and references to the document(s) used to generate the answer. QA document collections range from local text files to the entire World Wide Web. QA is more than a document search (*see* **Document Retrieval, Automatic**) in that it does not just return a list of documents, but rather returns exact answers. QA also differs from 'frequently asked question' (FAQ) matching systems that map a user question to one or more closely matching questions in a list of pre-answered questions.

Advanced QA systems are highly complex in that they typically involve many underlying technologies in natural language processing, including parsing (*see* **Parsing: Statistical Methods**), semantic analysis, named-entity recognition (*see* **Named Entity Extraction**), coreference resolution (*see* **Anaphora and Coreference Resolution, Statistical**), information retrieval, ontologies, paraphrasing, inferencing, and text generation. Widespread research in open-domain QA started in the late 1990s with significant new U.S. government funding and was fostered by the introduction in 1999 of a QA track at each international Text Retrieval Conference (*see* **Text Retrieval Conference and Message Understanding Conference**) at the U.S. National Institute of Standards and Technology (NIST), resulting in rapid advancements in the field, including evaluation standards, a large increase in publications, and strong performance improvements. The major components of a QA system are question analysis, information retrieval, and answer generation.

Question Answering from Text, Automatic

U Hermjakob, USC Information Sciences Institute, Marina del Rey, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Question answering (QA) is a natural language processing application (*see* **Natural Language Processing: Overview**) in which, given a question in plain natural language and a document collection, the computer system delivers an exact answer (i.e., without spurious text) to that question based on the document collection. The following examples are illustrative:

Question: How many people live in Los Angeles?
Answer: 3 912 200
Question: Who was Bach?
Answer 1: Johann Sebastian Bach, German baroque composer and organist, 1685–1750. One of the greatest . . .
Answer 2: Carl Philipp Emanuel Bach . . .
⋮
Answer 6: Edward Bach, British medical microbiologist, 1880–1936 . . .

General QA systems are open domain, i.e., there are no restrictions on the question type or topic. Answers can range from simple entities, such as names and quantities, to highly structured responses. Practical systems typically provide a ranked list of answers with some form of justification, e.g., with relevant extracts and references to the document(s) used to generate the answer. QA document collections range from local text files to the entire World Wide Web. QA is more than a document search (*see* **Document Retrieval, Automatic**) in that it does not just return a list of documents, but rather returns exact answers. QA also differs from 'frequently asked question' (FAQ) matching systems that map a user question to one or more closely matching questions in a list of pre-answered questions.

Advanced QA systems are highly complex in that they typically involve many underlying technologies in natural language processing, including parsing (*see* **Parsing: Statistical Methods**), semantic analysis, named-entity recognition (*see* **Named Entity Extraction**), coreference resolution (*see* **Anaphora and Coreference Resolution, Statistical**), information retrieval, ontologies, paraphrasing, inferencing, and text generation. Widespread research in open-domain QA started in the late 1990s with significant new U.S. government funding and was fostered by the introduction in 1999 of a QA track at each international Text Retrieval Conference (*see* **Text Retrieval Conference and Message Understanding Conference**) at the U.S. National Institute of Standards and Technology (NIST), resulting in rapid advancements in the field, including evaluation standards, a large increase in publications, and strong performance improvements. The major components of a QA system are question analysis, information retrieval, and answer generation.

Question Analysis

The initial question analysis serves to identify the type of answer, the type of question, and/or a list of search terms or strings. Knowing the type of answer can help greatly to reduce the space of possible answers. For the question *How tall is Mt. Everest?*, for example, the answer type would be *distance quantity*, possibly augmented with a heuristic range of typical value ranges that would eliminate any unreasonable values, such as *3 inches*. Answer types also support answer generation in helping to find the precise boundaries of the answer.

Answer-type detection patterns generally go beyond the surface form of a question, requiring a parse tree for a higher level of abstraction. Advanced QA systems support hundreds of answer types. For such answer types to be useful, the QA system must not only extract them from the question, but also must recognize them in text with answer candidates. Successful QA systems therefore critically rely on large and high-quality ontologies (such as WordNet; *see* **WordNet(s)**) and named-entity and quantity recognizers. Here are a few more examples of questions along with their classification:

Definition questions: What are invertebrates?
Why–famous questions: Who was Jane Goodall?
Abbreviation expansion: What does NAFTA stand for?
Date: When did the *Titanic* sink?
Temperature quantity: How hot is the core of the Earth?
Proper university: What is the most expensive university in the United States?
Noun phrase: What does the Peugeot company manufacture?

The granularity of answer types will vary from question to question. Though the question *How tall is Mt. Everest?* has a clear and narrow answer type (*distance quantity*), a question such as *What did Socrates say before he died?* leaves the range of possible answer types wide open. It can be useful to leave the answer type somewhat disambiguated, such as for the question *How long was Desert Storm?*, for which it might be safe to predict automatically an answer that is a *distance quantity* or a *temporal quantity*, but for which the final choice might be difficult without having a good understanding what type of thing *Desert Storm* might be. This is often unproblematic, because other components of a QA system will tend to eliminate of unreasonable type answers.

Another important function of question analysis is to identify question terms that will be useful for the document search. For a question such as *In what year did Columbus discover America?*, a good QA system will identify the question words *In what year* and auxiliaries such as *did* as much less likely to occur in a text passage containing the correct answer. Some systems build a ranking of search terms that are likely to be useful, and start a search by querying an information retrieval component over an initial set of question words. If search results turn out to be too numerous, the set can be augmented, and if there are too few results, question terms can be dropped. Some QA systems also offer a spelling-checking and correction capability.

Synonyms and Paraphrasing

Questions and the sentences that answer them often differ in words and structure, even to the point were there is no word overlap at all. The question *Who is the leader of France?* is not answered by the sentence *Henri Hadjenberg, who is the leader of France's Jewish community, endorsed confronting the specter of the Vichy past*, even though it contains all question words together and in order, but it is answered by *Bush later met with French President Jacques Chirac*, even though there is no word overlap at all.

To increase the chances of finding a good answer, a QA system will often substitute question terms with synonyms, drawing on resources such as WordNet. In the question *When did the United States buy Alaska?*, the word *buy* could be replaced by *purchase* or even the more general *acquire*, resulting in an good match with *The United States purchased Alaska in 1867*. Question reformulation is, however, not limited to single words. Advanced QA systems will paraphrase entire sentences. The question *What's the price of a Volkswagen Beetle?* can be recast as *How much does a Volkswagen Beetle cost?* In order to achieve this, the QA system will draw on a paraphrase resource that will assert the equivalence of *What's the price of X?* and *How much does X cost?*, possibly restricting the syntactic and semantic category of any X. Such resources can be built either by hand or automatically. Manual efforts are feasible for question answering because a relatively small class of question types tends to account for a relatively large number of questions that people tend to ask, and for any such question type, a limited number of paraphrases will account for a relatively large number of successful paraphrases. Human intuition and time, however, have their limits, and some of the best patterns might not immediately come to mind on introspection. Consider, for example, questions such as *When was Mozart born?* One successful approach in learning useful paraphrases is to look for text passages for a few

examples of key question terms ('Mozart') along with their known answers ('1756'), or 'Einstein'/'1879.' A paraphrase harvester would look for common patterns, including question and answer terms, and then statistically identify patterns that link the two frequently. In a subsequent phase, the system might use question terms and pattern candidates to find answers and then rank the patterns according to how reliable their results are for known answers. Such an approach would not only find the obvious *X was born in Y* pattern, but also the very productive pattern *PERSON (YEAR–YEAR)*, as in *Mozart (1756–1791)*.

A simple type of paraphrasing that is nevertheless very helpful is syntactic transformation. A question such as *When did the Titanic sink?* can be mapped to *The Titanic sank when?* or even to *The Titanic sank on what day?* Using a search engine to locate documents containing the string *The Titanic sank on* will tend to deliver very focused results. Classic paraphrasing and syntactic transformations can easily be combined, so that a question such as *How did Gandhi die?* might be paraphrased as *Gandhi died from what?*, *Gandhi committed suicide?*, *Gandhi was assassinated by who?*, and many more. As would be expected, many paraphrases will not yield any answers, but one good strike is often sufficient. Note that paraphrases of a sentences do not necessarily fully preserve the meaning, but might be more specific. An answer to the specific question (*Gandhi was assassinated by who?*) will also be an answer to the more general question, which can be viewed as a form of inference. Note that questions are not always questions in a strict syntactic sense. The query *Name the countries on the UN Security Council* has to be understood as a question, as does the even more terse *Countries on the UN Security Council*.

Identifying the type of question can be very important, even if the answer cannot be narrowed down to a specific semantic or syntactic type. QA systems often contain specialized submodules to deal with specific types of questions, such as biography questions (*Who was Bach?*), causal questions (*Why is the dollar so weak?*), and conversion questions (*How much is 20°C in Fahrenheit?*).

Information Retrieval

The better the question analysis, the easier it will be for a search engine such as Google or a traditional information retrieval (IR) module to deliver useful answer candidates. Besides the techniques already mentioned, QA systems also often employ classical IR techniques such as stemming and eliminating stop words. Consider the following example:

Question: Which languages does Putin speak?
Paraphrase resource (one of several relevant sections):
:anchor-pattern 'SOMEBODY 1 speaks LANGUAGE 2.'
:can-be-inferred-from 'SOMEBODY 1 is fluent in LANGUAGE 2.'
Paraphrases:
Putin speaks <which language>?
Putin is fluent in <which language>?
Search engine calls (selection):
Putin speaks
Putin is fluent in
Putin speaks (*set of words as fallback*).
Search engine results (selection):
Putin speaks of new world order.
Putin speaks with university students.
Mr Putin is fluent in English and German.
Answer: Putin is fluent in **English and German**.

Another approach is to preprocess a document collection or, in the case of very large document collections such as the World Wide Web, at least part of the collection. An index of words is often augmented by an index of more general types, such as *distance quantity*, *proper country*, or *component of a weapon of mass destruction*. An index supporting the last two types would make it much easier to find passages that might answer a question such as *Which countries have sold biological warfare agents during the past 5 years?* To take preprocessing even a step further, some systems actively scan through large collections of texts, mining facts that are then stored in databases, which can then later be used to answer certain types of questions very quickly by drawing on a precompiled cache of answers.

Answer Selection and Generation

After a search engine returns a set of documents, a QA system first has to narrow down the text space by identifying shorter passages, of a few sentences, that contain a sufficiently high concentration of question terms, and also to make sure that the passage includes phrases of the proper answer type. QA systems then proceed to apply deeper natural language processing techniques such as parsing. To select the proper answer to the question *Who killed John F. Kennedy?*, the QA system cannot always solely rely on matching words without context, as the two following answer candidate sentences illustrate:

1. Belli's clients have included *Jack Ruby*, who killed John F. Kennedy assassin Lee Harvey Oswald, and Jim and Tammy Bakker.
2. On Nov. 22, 1963, the building gained national notoriety when *Lee Harvey Oswald* allegedly shot

and killed President John F. Kennedy from a sixth-floor window as the presidential motorcade passed the site.

A simplistic system might prefer the answer from sentence 1, *Jack Ruby*, because the answer is closer to the question search terms *killed* and *John F. Kennedy*, but a system that parses both question and answer would prefer the answer from sentence 2, *Lee Harvey Oswald*, because it satisfies matching semantic relations for both the predicate and logical subject (*kill*, *who/Lee Harvey Oswald*) and for the predicate and logical object (*kill, John F. Kennedy*).

Semantic relation matching can also be viewed as 'proving' an answer by mapping both the question and answer into some sort of logical form and then using 'theorem proving' techniques to establish the validity of an answer. Both approaches require parsing, and both gain robustness by not necessarily requiring that all relations match. This can be implemented by awarding points rather than by requiring strict matching of all parts of a question, or by 'relaxing' a proof by allowing the system to drop parts of a clause. Another critical component of a good QA system is coreference resolution. To answer the question *Where is the Finsbury Park mosque?* using the text passage *Finsbury Park mosque has been called the hub of Islamic extremism in Britain. It is located in northern London,* the confidence in the answer *northern London* is greatly increased by identifying *Finsbury Park mosque* as the antecedent of *It*. Similarly, in order to better support follow-up questions such as *Who is the leading producer of diamonds?* (*De Beers*) – *Who owns the company?*, a system needs to resolve *the company* as referring to *De Beers*. Another important type of resolution involves relative time expressions, as in *Johnny Carson died Sunday of complications from emphysema*, in which *Sunday* needs to be resolved to an absolute date based on the date of the article.

QA systems often eliminate some bad answers by using a set of answer filter heuristics. An example of such a heuristic is to prefer answers that contain something substantially novel. For the question *Where in Austin is Barton Springs?*, this would clearly rule out the answer *Austin*. The heuristic can theoretically backfire in trick questions such as *What condiment is made from mustard seed?*, but it is generally quite helpful. Other heuristics eliminate answer candidates with kiss-of-death modifiers such as a negation adverb, or modifiers such as *second* in *second tallest*, when these modifiers do not also occur in the question. Furthermore, answers generally need to be specific enough, e.g., need to include a proper noun for location questions, and questions themselves generally do not make for good answer material.

Structured answers are not only useful for ambiguous questions such as *Where is the Taj Mahal?*, which might refer to the architectural masterpiece in India or to the casino of the same name in Atlantic City, New Jersey, but can also be helpful to allow the user to skip over a whole cluster of incorrect answers, or to better gauge how many different documents might support the same answer, thereby increasing confidence in its correctness in a quantitative way.

Justification

Practical QA systems justify their answers with relevant extracts and references to the document(s) used to generate the answer. Such justification is important to show that an answer is indeed correct and to let the user know how current and reliable the source is and how strongly the answer is corroborated by other sources. The context of an answer also often provides additional information that a user might find useful.

Answering Questions from Nontextual Resources

Some questions do not lend themselves very well to textual search:

- What is 105°F in Celsius?
- How much is 40 million Euros in U.S. dollars?
- What does AWACS stand for?
- How do you say 'thank you' in Czech?
- When is Easter next year?
- What is the current time in Moscow?

Based on a relatively limited number of patterns, a QA system can identify special question types, such as quantity conversion, and a few types of calendar and time questions. Rather than proceeding with an information retrieval step, the QA system would call a special function with proper arguments or would refer to specialized Websites that perform tasks such as conversions between different currencies. Calls to such Websites might include arguments extracted from the question, such as the source currency amount and target currency unit, so that the Website will deliver the specific answer that the user was seeking. In other cases, the system might be able to map a question to a table lookup or database query, including dictionaries, factbook tables, WordNet definitions, and abbreviation lists.

Research Directions

Besides work to further improve critical components of QA systems such as parsers, named-entity taggers,

and ontologies, recent research has focused on increasingly automating the acquisition of knowledge and query reformulation patterns, combining results from different QA approaches, decomposing complex questions into simpler ones, and then building the overall answer from pieces of information from different sources or even different types of resources (such as natural language text and structured knowledge bases). Other challenges include interactive question answering, whereby a user would navigate a context-conscious system gradually toward an answer, and cross-lingual question answering, in which answers are retrieved from documents in a language different from the language of the question.

Antonio Quilis Morales was born in Larache (Morocco), on September 3, 1933. He obtained his undergraduate degree and his doctorate in Arts (Romance philology) at the Complutense University of Madrid. He received an Extraordinary Award, given to the top few students in a Spanish university graduating class, for both degrees, with his doctorate thesis being *El encabalgamiento en la métrica española*.

Beginning in 1960, he collaborated with the CSIC (Superior Council of Scientific Investigations). At first, he was the temporary Head of the Phonetics Section and the Phonetics Research unit, and after that he became an occasional collaborator, a scientific collaborator (1962) and a scientific researcher (1966). From 1963 he was the head of the Phonetics Department. Regarding his career as a phonetician, and following the advice of his Spanish tutor, Rafael de Balbín, Quilis was trained in Strasbourg by Georges

and ontologies, recent research has focused on increasingly automating the acquisition of knowledge and query reformulation patterns, combining results from different QA approaches, decomposing complex questions into simpler ones, and then building the overall answer from pieces of information from different sources or even different types of resources (such as natural language text and structured knowledge bases). Other challenges include interactive question answering, whereby a user would navigate a context-conscious system gradually toward an answer, and cross-lingual question answering, in which answers are retrieved from documents in a language different from the language of the question.

Quilis, Antonio (1933–2003)

J Carrera-Sabaté, University of Barcelona, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Antonio Quilis Morales was born in Larache (Morocco), on September 3, 1933. He obtained his undergraduate degree and his doctorate in Arts (Romance philology) at the Complutense University of Madrid. He received an Extraordinary Award, given to the top few students in a Spanish university graduating class, for both degrees, with his doctorate thesis being *El encabalgamiento en la métrica española*.

Beginning in 1960, he collaborated with the CSIC (Superior Council of Scientific Investigations). At first, he was the temporary Head of the Phonetics Section and the Phonetics Research unit, and after that he became an occasional collaborator, a scientific collaborator (1962) and a scientific researcher (1966). From 1963 he was the head of the Phonetics Department. Regarding his career as a phonetician, and following the advice of his Spanish tutor, Rafael de Balbín, Quilis was trained in Strasbourg by Georges

Straka and then he founded the first experimental phonetics laboratory in Spain, where he worked for more than 40 years and where he updated the research that Tomás Navarro Tomás had taken over at the beginning of the 20th century.

He began teaching at the University of Madrid in 1967 as an assistant professor of Spanish. In 1970 he obtained the Chair in the historical grammar of Spanish at the University of Seville. One year later, he won the Chair in history of Spanish at the University of Valladolid. In 1975 he became chair of Spanish at the Universidad Nacional de Educación a Distancia (UNED), where he worked until his retirement in 2003. There, he was head of the Spanish Department and Dean of the College of Arts. In 1993, he was awarded the Medal of the UNED for his outstanding work.

Apart from his teaching experiences in Spain, he was a visiting professor in many universities and research centers in Europe and the Americas. In addition, he taught Spanish to teachers from the Philippines (for 22 years) and teachers from Latin America (for 42 years) in the Institutes of Hispanic Culture and Latin-American Co-operation. Professor Quilís also delivered more than 60 conferences in universities and research centers around the world and supervised more than 40 doctoral theses during his career.

Without any doubt, the most well-known scientific work by Quilis is in the field of phonetics. Some of his books, with many editions, are: *Fonética acústica de la lengua española* (1981), *Tratado de fonología y fonética de la lengua española* (1993), *Curso de fonética y fonología españolas para estudiantes angloamericanos* (1964) (with Joseph A. Fernández), *Principios de fonología y fonética españolas* (1997), and *Comentario fonológico y fonético de textos* (1985). From his experimental work we can highlight the reasoning of instrumentation through hypotheses based on theoretical patterns (see Cerdà, in press). Furthermore, he worked in forensic phonetics, applied mostly to voice identification, and was considered to be the foremost Spanish specialist in voice identification. Moreover, as an expert in legal voice identification, he organized and taught several forensic phonetics courses to teams of police scientists.

Together with phonetics, he worked in Hispanic dialectology; he carried out enormous fieldwork, traveling around the world and collecting extraordinarily valuable material. From 1985, with Manuel Alvar, he co-ordinated the work on the *Atlas Lingüístico de Hispanoamérica*, a continent-encompassing, analytical atlas. The scope they wanted to achieve with the data obtained was twofold: to solve problems such as the establishment of dialectal zones in Latin America, and to supply language information from wide areas of this continent that were under research. Although the atlas is not yet finished, complete fieldwork has been done in 14 countries, such as Puerto Rico, Cuba and Panama.

He studied the Spanish of the Philippines, Micronesia, and Equatorial Guinea, and in 1992, he began managing the preparation of the *Atlas Lingüístico Nacional del Ecuador* together with Celia Casado. Concerning the dialectology of the Iberian Peninsula, he led the study of educated speech of Madrid for many years.

Professor Quilis worked, furthermore, in other philological fields, such as metrics, publishing *Métrica española* (1969) stemming from his doctoral thesis; language history (*Historia de la lengua española*, 1976); and linguistic historiography (*Antonio de Nebrija: gramática de la lengua castellana*, 1980). He also worked in lexicography; first-language teaching; interference in the speech of immigrants' children; the comparison of Spanish with other languages; speech therapy; and the study of several languages, such as Chamorro, Nugunu (Cameroon), Tagalog and the Portuguese of Brazil.

Starting in 1965, he was a collaborator with the Centre de Philologie et Littératures Romanes at the University of Strasbourg, a member of the Orden Civil de Alfonso X El Sabio and, since 1966, a participant on the executive committee of a project to study the educated speech of the principal cities of Latin America and the Iberian Peninsula. He was president of the Spanish Linguistics Society between 1974 and 1978, honorary member of the Philippine Academy of Language, Conseiller du Bureau de la Société de Linguistique Romane, full member of the Instituto de Estudios Madrileños, and honorary member of the Sociedad Española de Lingüística (2000). He was given the Inventor-Innovator Award of the journal *Mundo electrónico* (1983), received the Medal of the Hankuk University of Foreign Studies in Seoul (1984) and, in 1999, received the Gran Cruz de la Orden de Alfonso X el Sabio. Since 2000, he had been the editor of the *Revista de Filología Española*.

Professor Quilis died in Madrid on December 8, 2003, a few weeks after retiring and with a large number of projects to accomplish. His life was entirely dedicated to the teaching and research of Spanish, as we can see in his nearly 300 publications and his more than 70 contributions to scientific congresses, all of them elaborated tenaciously and regularly throughout his academic career.

Quine, Willard van Ormand (1908–2000)

B Sypniewski, Rowan University, Camden Campus, Camden, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Willard van Ormand Quine (1908–2000) was the Edgar Pierce Professor of Philosophy, Emeritus, at Harvard University. Quine was one of the major figures in American logic and wrote several standard texts on the subject. While not a linguist, Quine came from the Logical Positivist School of logic and philosophy, which sees philosophy in terms of language use. The logical positivists have exerted a substantial influence on modern linguistics, not on grammar *per se*, but on their emphasis on the structure of thought and notions such as Wittgenstein's 'language games.'

Logic since Frege has developed along symbolic lines. Logical abstraction developed so that the structure of thought could become clearer upon examination. This meant that the effects of language, which was seen as a significant problem, needed to be eliminated. Previous schools of logic, such as Aristotelian syllogistic, also recognized the potentially deleterious effects that language could have on logical thought. Rather than eliminating natural language, they sought to limit the harm by limiting the admissible language and strictly defining the form of expressions.

Twentieth-century symbolic logic became a powerful tool by becoming semantic free. However, a simultaneous development, often among the same groups that were developing predicate calculus, examined the use of language in philosophy and everyday thought. As such, a tension developed between pure logic and the philosophy of language. Quine is a good example of that tension.

Quine's major contribution to the philosophy of language was *Word and object* (1960). We can see the effects of logical positivism as early as the dedication to Rudolph Carnap, a major figure in the development of logical positivist language theory. Quine begins his treatise by examining sense data. Quine asserts that "there is no justification for collating linguistic meanings, unless in terms of men's dispositions to respond overtly to socially observable stimulations" (Quine, 1960: ix). He briefly examines language learning, acknowledging that words are learned "in context" (1960: 13) but ignoring context for the rest of the book. While Quine did not say so explicitly, he treats learning a collection of words as equivalent to learning language. His idea seems to be that since sentences, the basic units of language, are structured collections of words, language can be logically divided into words and structure, with the units of structure (something like grammar) being a smaller collection than the lexicon. Structure is somehow 'basic' to the human; words are learned. In his later *Philosophy of logic*, Quine claimed that to have learned a language, one must have learned its grammar; vocabularies may differ from person to person but the grammar remains

Willard van Ormand Quine (1908–2000) was the Edgar Pierce Professor of Philosophy, Emeritus, at Harvard University. Quine was one of the major figures in American logic and wrote several standard texts on the subject. While not a linguist, Quine came from the Logical Positivist School of logic and philosophy, which sees philosophy in terms of language use. The logical positivists have exerted a substantial influence on modern linguistics, not on grammar *per se*, but on their emphasis on the structure of thought and notions such as Wittgenstein's 'language games.'

Logic since Frege has developed along symbolic lines. Logical abstraction developed so that the structure of thought could become clearer upon examination. This meant that the effects of language, which was seen as a significant problem, needed to be eliminated. Previous schools of logic, such as Aristotelian syllogistic, also recognized the potentially deleterious effects that language could have on logical thought. Rather than eliminating natural language, they sought to limit the harm by limiting the admissible language and strictly defining the form of expressions.

Twentieth-century symbolic logic became a powerful tool by becoming semantic free. However, a simultaneous development, often among the same groups that were developing predicate calculus, examined the use of language in philosophy and everyday thought. As such, a tension developed between pure logic and the philosophy of language. Quine is a good example of that tension.

Quine's major contribution to the philosophy of language was *Word and object* (1960). We can see the effects of logical positivism as early as the dedication to Rudolph Carnap, a major figure in the development of logical positivist language theory. Quine begins his treatise by examining sense data. Quine asserts that "there is no justification for collating linguistic meanings, unless in terms of men's dispositions to respond overtly to socially observable stimulations" (Quine, 1960: ix). He briefly examines language learning, acknowledging that words are learned "in context" (1960: 13) but ignoring context for the rest of the book. While Quine did not say so explicitly, he treats learning a collection of words as equivalent to learning language. His idea seems to be that since sentences, the basic units of language, are structured collections of words, language can be logically divided into words and structure, with the units of structure (something like grammar) being a smaller collection than the lexicon. Structure is somehow 'basic' to the human; words are learned. In his later *Philosophy of logic*, Quine claimed that to have learned a language, one must have learned its grammar; vocabularies may differ from person to person but the grammar remains

the same. "For it is only lexicon, not grammar, that registers differences in background from speaker to speaker; and the logical truths stay true under all lexical substitutions" (Quine, 1970: 101).

Word and object is primarily about the theory of reference. Quine looks at translation as a way of examining reference. By 'translation,' he does not strictly mean the translation between languages, although that is included in his discussion. 'Translation' means, primarily, reducing our sense stimuli to language. Note that Quine was influenced by Skinner and often used 'verbal behavior' as a neutral term. *Word and object* was written shortly after Skinner's *Verbal behavior* and the controversy that Chomsky's review of that book created. Read carefully, Quine comments unfavorably on Chomsky's criticisms. Be that as it may, Quine created a famous thought experiment, sending a linguist to the 'darkest archipelago' to learn a hitherto unknown tribe's language without the aid of an interpreter. Quine admitted that this situation is unrealistic but postulated it as a way of elucidating his discussion of translation. While in the field with an informant, the linguist sees a rabbit scurry by and hears the informant utter "gavagai." The linguist begins his study by equating 'gavagai' roughly with 'rabbit.' While this may seem straightforward, Quine notes that it is not, because the informant may not strictly mean 'rabbit' but, perhaps, 'white rabbit,' 'Lo, the rabbit,' or some other variant. Quine claims that the linguist should not equate words to each other but should assign words to equivalent stimulations. He notes that the utterance might be affected by what temporally proceeds or follows the stimulation. Because of this, reference is not a simple philosophical or linguistic problem.

Much of the rest of the book can be seen as a detailed discussion of the problem of reference. Quine does not delve significantly into the linguistic aspects of reference but builds a theory of reference on logical foundations. In passing, Quine dismisses discussions of many types of sentences that would be of interest to linguists and focuses almost entirely on sentences that could be reduced to logical propositions, i.e., sentences that are either logically true or false.

At the end of the book, Quine briefly sets out his notion of 'semantic ascent.' Returning to the problems that natural language poses for logic and philosophy, Quine questions Carnap's claim that philosophical questions are ultimately questions of language, i.e., questions about what is, and not "questions about extralinguistic reality" (Quine, 1960: 271). Quine asks why this should be true of only philosophical questions and not theoretical ones. Discussing unicorns is a discussion about something that doesn't exist; he notes that a discussion of points, miles, and other such mathematical devices is also a discussion about things that do not exist. Yet we recognize these discussions as being different. The difference is caused by 'semantic ascent,' which he calls a 'manoeuvre.' "The strategy of semantic ascent is that it carries the discussion into a domain where both parties are better agreed on the objects (viz. words) and on the main terms concerning them"(Quine, 1960: 272).

Quine presented the linguist with standard logical thought. His system of logic was standard. His comments on reference were standard. They were not the result of examining a linguistic corpus but of developing a theory of logic. Quine believed that logic and grammar are paramount. Natural language and human communication as we know it are built upon these foundations and are ultimately reducible to them.

Quintilian (ca. 30–98 A.D.)

D J Taylor, Lawrence University, Appleton, WI, USA

© 2006 Elsevier Ltd. All rights reserved.

Quintilian's is arguably the most famous name in the history of rhetoric. Born in Calagurris, modern Cahorres, near Barcelona, around 40 A.D. and educated in Rome by the rhetorician Domitius Afer and may be – the information is somewhat suspect – the grammarian Quintus Remmius Palaemon, he returned to Spain and so distinguished himself in the courts that Galba, the Roman provincial governor, took Quintilian with him when he entered Rome as emperor in 68 A.D. There Quintilian achieved unparalleled success as an orator and teacher of rhetoric: his clients included Queen Berenice of Egypt and his students, Pliny the Younger; he amassed considerable wealth and fame; he was the first professor to earn a salary from the imperial treasury; he was appointed tutor to Domitian's nephews, whom the emperor was training to succeed himself; and his *magnum opus* and only extant work, the *Institutio Oratoria*, written after his retirement from teaching in 88 A.D., remains the classic text on rhetoric and the education of orators. His young, beloved wife and their two boys died young, and Quintilian himself died around 96 A.D.

The 12 books of the *Institutio Oratoria* describe Quintilian's ideal educational program designed to produce a master orator, beginning with the child in the cradle and continuing until the "good man skilled in speaking" retires from the public forum. Paradoxically, the two most famous sections of the *Institutio* deal with grammar and literature, in books 1 and 10, respectively. Quintilian's sketch of the grammatical curriculum (I.4-9) in Roman education is the earliest and most comprehensive account of grammar in its entirety in either the Roman or the Greek world and is therefore of crucial importance for the history of linguistics. Quintilian's sketch may be ideal rather than actual, but it does compare favorably with literary references in Juvenal and Seneca.

Grammar is both linguistic (*recte loquendi scientia*) and literary *(poetarum enarratio)*; grammatical education therefore encompasses both speaking and writing and begins with phonetics and the alphabet. It proceeds to the word level and treats derivation, the parts of speech, declension and conjugation, and ambiguous words. (Quintilian understands rhotacism but not declensional or conjugational affiliations, enumerates several different competing systems of *partes orationis*, and avers that the instrumental ablative is neither a true Latin ablative nor a true Greek dative.) The grammarian then addresses the vices and virtues of speech; Quintilian's description of barbarisms and solecisms is especially noteworthy. Principled linguistic behavior is a matter of reason, antiquity, authority, and usage. The sketch concludes with literary matters: orthography, reading (aloud, of course), figures, style, historical and mythological minutiae, and composition exercises. The organization of Quintilian's grammatical account in the *Institutio Oratoria*, especially its tripartite arrangement (phonology, morphology, *vitia virtutesque orationis*), therefore looks quite like that of a much later *ars grammatica* and suggests that the Roman *ars* had already assumed or was in the process of assuming its canonical form.

Quirk, Professor The Lord Charles Randolph (b. 1920)

N Kerecuk, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Professor Randolph Quirk (Figure 1), a British grammarian and linguist, was born in the Isle of Man, educated at University College London (UCL) and received a B.A., an M.A., a Ph.D., and a D.Litt. there. He was a lecturer in English (1947–1952) at UCL; a reader in English Language and Literature (1954–1958) and a Professor of English Language (1960–1968) at the University of Durham; and a Quain Professor of English Language and Literature at UCL (1968–1981). In 1972, he chaired a Government Committee of Enquiry in Speech Therapy Services for the reform of training of speech therapists in the UK. He also served as the Vice-Chancellor of the University of London (1981–1985), as a member of the board of the British Council (1983–1991), as Chairman of the British Library advisory Committee (1984–1997), as President of the British Academy (1985–1989), and as Trustee of the Wolfson Foundation (1987). He was awarded the CBE in 1976, knighted in 1985, and made a life peer in 1994.

Professor Quirk's scholarly activities span a wide-ranging set of topics in English language and related subjects, for example: grammar in general, descriptive grammar, phonology, morphology, vocabulary, and syntax of English, including Old, Middle, and Modern English; editions of Old Icelandic texts; the language of Dickens and Shakespeare; teaching of English; mother-language and foreign-language teaching; lexical studies of English; the role of English as an international language; and English-language usage, including Old English varieties of English.

Figure 1 Professor The Lord Charles Randolph Quirk (Baron Quirk of Bloomsbury).

In the context of English-language usage, Professor Quirk was the founder of the Survey of English Usage (1959) and directed this research project until 1981. The research aimed at collecting, compiling, and analyzing a corpus of written and spoken language used by adult native speakers of British English. Professor Quirk also developed techniques for eliciting usage and attitude to usage by the speakers that the participants of the survey applied. The data collected in this corpus has enabled many researchers worldwide to produce various analyses and to carry out various experiments; many publications have ensued.

Professor Quirk, in collaboration with other grammarians, published two major reference grammars: *A grammar of contemporary English* (Quirk *et al.*, 1972) and a major compendium, *A comprehensive grammar of English language* (Quirk *et al.*, 1985). In addition, he wrote *A communicative grammar of English* and *A university grammar of English* (1973) (published in a shorter version in the United States as *A concise grammar of contemporary English*). Professor Quirk's team includes Sidney Greenbaum, Greffrey Leech, and Jan Svartvik; they started their work on grammars in the 1960s and planned to produce a series of grammars. Their *Communicative grammar of English* (Leech and Svartvik, 1975): "looks at the whole grammar from a semantic and communicative viewpoint" (1985: v).

A comprehensive grammar of English language (1985) was described by the authors as the culmination of their joint efforts. It also represented an advancement of the research into the grammatical structure, description of English, and the developments in linguistic theory as pursued by many scholars around the world. The contents page offers an insight into the eclectic theoretical approach adopted by the authors. The first chapter contains (1) a description of the current state and status of the English language, (2) a section of grammar and study of language, and (3) a comprehensive description of the varieties of English used both by an individual and by English speech communities. The second part of Chapter 1 'Grammar and the study of language' (1.12 to 1.18) is a statement of what grammarians mean by

'grammar' and defines the scope of descriptive grammar. Grammar was understood in the sense of the inclusion "of both SYNTAX and that aspect of MORPHOLOGY (the internal structure of words) that deals with INFLECTIONS (or ACCIDENCE)" (1985: 12). The authors explained that there are various types of grammar organization and commented that they did not want to state that phonology is independent from grammar, as the two are interdependent, that there is a difficulty in drawing a borderline between grammar and semantics and pragmatics. They were not concerned with theoretical matters. They stated: "Our general principle will be to regard grammar as accounting for constructions where greatest generalization is possible, assigning to lexicology (and hence beyond the scope of this book) constructions on which least generalization can be formulated" (1985: 15).

The second chapter of *A comprehensive grammar of English language* offers a 'Survey of the English Grammar,' outlines the structure of the English sentence, and aims to provide a general introduction and introduce concepts and categories necessary for the whole grammar.

The other chapters represent an innovative approach to descriptive grammar and include the description of the grammatical categories and parts of speech, phrases, and sentence structure and function. The chapter 'Theme, Focus, and Information Processing' (1985: 1353–1420) contains prosodic and grammatical aspects, postponement, existential sentences, emotive emphasis, and reinforcement. The last chapter, 'From Sentence to Text,' offers pathways to text analysis by describing the context of the notion of text and the connective and grammatical devices that can be employed, as well as features of pragmatics, semantics, and grammar with illustrative examples. There are three appendices: (1) word formation, (2) stress, rhythm, and intonation, and (3) punctuation.

A comprehensive grammar of English language has an added interest in that it represents an innovative development in terms of approaches to grammar writing with the conceptual framework that underlies the process. Equally, it contains a thorough record of the state of the English language (the common core), with its varieties and styles, in the second half of the 20th century.

The grammatical works of Professor Quirk have been used for native-language speakers and very broadly for the teaching of English as a second and/or foreign language throughout the world. Teacher training courses for EFL (English as a foreign language) teachers everywhere regard the study of his grammatical works as an essential component of their teacher education programs. Histories of ideas in linguistics have not yet pursued research into the heritage of this grammarian.

Professor Quirk is a crossbencher in the House of Lords. He was married to Jean Williams (they divorced in 1979; she died in 1995) and has two sons. He has been married since 1984 to Gabriele Stein.

Qur'an

Y Wahyudi, Tufts University, Medford, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Muhammad received his first revelation at the Cave of Hira' near Mecca on Ramadan 17th, 610 C.E. "Read!" was Gabriel's order to him, who replied, "I cannot read." He repeated his answer "I cannot read" to Gabriel's second order. However, he replied, "What can I read?" to Gabriel's more terrible third command. Gabriel then said:

> "Read: in the name of your Lord Who Created.
> "Created man from a clot.
> "Read: And it is your Lord the Most Beautiful
> "Who taught by the pen,
> "Taught man that which he did not know." (Q. 96: 1–5).

Subsequently, Muhammad received his respective Meccan (610–620) and Medinan (620–632) revelations – known as the Qur'an, whose language serves as Muslim ritual language. At least five times a day, Muslims everywhere recite the Arabic Qur'an in their prayers, making it the language that unifies Muslims. Indeed, the Muslim world holds International Qur'anic Reciting Contests in which may be found competitions in Memorizing the Qur'an and Reciting the Qur'an (the latter stresses the beauty and music of Qur'anic recitation).

Because Muhammad was 'illiterate' (*ummī*) and lived in an illiterate society, the Qur'an's eloquence was a miracle. It would have been impossible for him, Muslims argue, to have composed this beautiful Book. However, al-Nazzam (d. 835), a leading philosopher of Mu'tazilism (Islamic rationalism), disregarded the Qur'an's eloquence as a miracle. If it were not for the fact that God had not prevented the Arabs from doing so, they would have been able to imitate and even surpass the literary style of the Qur'an. This theory of God's intervention he called *al-ṣarfa*, and it was the *ṣarfa* itself and the Qur'an's information about the hidden that constituted Muhammad's miracles. If the *ṣarfa* were a miracle, Muslims criticized al-Nazzam, the challenge of the Qur'an would be quite meaningless, whereas the divine text made the challenge increasingly easier. This is in reference to the Qur'an's challenge to human beings in 17: 88 to produce its like. If they were unable to compose something that equaled the entire Qur'an, the Scripture challenged them to produce ten chapters (Q. 11: 13 and 14) and even a single chapter (Q. 2: 23–24 and 10: 38). Because the challenge was not fulfilled, Muslims made it a miracle of the Qur'an.

The second dimension of the miraculous nature of the Qur'an is it speaks about later events and later discoveries. In Q. 10:92, for example, we are informed that God "preserves the dead body of Pharaoh for posterity." The story of his body was completely unknown to 7th-century Arabia, yet, miraculously, the French archeologist Victor Loret discovered the dead body of this Pharaoh in the Valley of the Kings (Luxor, Egypt) in 1896. Indeed, his body was intact when the archeologist Elliot Smith took off the mummy's wrappings on July 8, 1970. As for the Qur'an's information about the not yet discovered, one can point to the passage: "We send the winds *lawāqiḫ* (that fertilize) . . ." (Q. 15: 22). Fertilization (*liqāḫ*: singular of *lawāqiḫ*), for ancient commentators of the Qur'an, was pregnancy. They therefore interpreted the winds as containing clouds or the rain within the clouds. This interpretation was of little significance because the wind just moves the clouds from place to place – it does not contain them. However, modern botany has discovered that plants such as grain, orange, and pomegranate trees need fertilization for their production, and that fertilization often occurs through the winds. When blossoms ripen, their seeds are released and spread by the winds, so that they fall on other flowers.

There are many other examples of the Qur'an's containing information about knowledge discovered only recently. Many of his contemporaries accused

Qur'an

Y Wahyudi, Tufts University, Medford, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Muhammad received his first revelation at the Cave of Hira' near Mecca on Ramadan 17th, 610 C.E. "Read!" was Gabriel's order to him, who replied, "I cannot read." He repeated his answer "I cannot read" to Gabriel's second order. However, he replied, "What can I read?" to Gabriel's more terrible third command. Gabriel then said:

> "Read: in the name of your Lord Who Created.
> "Created man from a clot.
> "Read: And it is your Lord the Most Beautiful
> "Who taught by the pen,
> "Taught man that which he did not know." (Q. 96: 1–5).

Subsequently, Muhammad received his respective Meccan (610–620) and Medinan (620–632) revelations – known as the Qur'an, whose language serves as Muslim ritual language. At least five times a day, Muslims everywhere recite the Arabic Qur'an in their prayers, making it the language that unifies Muslims. Indeed, the Muslim world holds International Qur'anic Reciting Contests in which may be found competitions in Memorizing the Qur'an and Reciting the Qur'an (the latter stresses the beauty and music of Qur'anic recitation).

Because Muhammad was 'illiterate' (*ummī*) and lived in an illiterate society, the Qur'an's eloquence was a miracle. It would have been impossible for him, Muslims argue, to have composed this beautiful Book. However, al-Nazzam (d. 835), a leading philosopher of Mu'tazilism (Islamic rationalism), disregarded the Qur'an's eloquence as a miracle. If it were not for the fact that God had not prevented the Arabs from doing so, they would have been able to imitate and even surpass the literary style of the Qur'an. This theory of God's intervention he called *al-ṣarfa*, and it was the *ṣarfa* itself and the Qur'an's information about the hidden that constituted Muhammad's miracles. If the *ṣarfa* were a miracle, Muslims criticized al-Nazzam, the challenge of the Qur'an would be quite meaningless, whereas the divine text made the challenge increasingly easier. This is in reference to the Qur'an's challenge to human beings in 17: 88 to produce its like. If they were unable to compose something that equaled the entire Qur'an, the Scripture challenged them to produce ten chapters (Q. 11: 13 and 14) and even a single chapter (Q. 2: 23–24 and 10: 38). Because the challenge was not fulfilled, Muslims made it a miracle of the Qur'an.

The second dimension of the miraculous nature of the Qur'an is it speaks about later events and later discoveries. In Q. 10:92, for example, we are informed that God "preserves the dead body of Pharaoh for posterity." The story of his body was completely unknown to 7th-century Arabia, yet, miraculously, the French archeologist Victor Loret discovered the dead body of this Pharaoh in the Valley of the Kings (Luxor, Egypt) in 1896. Indeed, his body was intact when the archeologist Elliot Smith took off the mummy's wrappings on July 8, 1970. As for the Qur'an's information about the not yet discovered, one can point to the passage: "We send the winds *lawāqiḫ* (that fertilize) . . ." (Q. 15: 22). Fertilization (*liqāḫ*: singular of *lawāqiḫ*), for ancient commentators of the Qur'an, was pregnancy. They therefore interpreted the winds as containing clouds or the rain within the clouds. This interpretation was of little significance because the wind just moves the clouds from place to place – it does not contain them. However, modern botany has discovered that plants such as grain, orange, and pomegranate trees need fertilization for their production, and that fertilization often occurs through the winds. When blossoms ripen, their seeds are released and spread by the winds, so that they fall on other flowers.

There are many other examples of the Qur'an's containing information about knowledge discovered only recently. Many of his contemporaries accused

Muhammad of being crazy for relating unproven scientific information, but God firmly insisted that he was not crazy (Q. 68: 1 and 81:22) and that he communicated only revelation (Q. 53: 2–3). Modern Muslim thinkers call the Qur'an's hidden scientific information the 'scientific miracle' in the sense that they point to scientific discoveries to prove that the Qur'an was God's words and not Muhammad's, as it would have been impossible for the latter to possess such advanced knowledge unless it came from God. Because it is not a book of science, but a divine guidance, the Qur'an expresses its scientific miracles in theological and moral paradigms, as is the case with the aforementioned verse, which ends in "but you are not the keepers of its store" (Q. 15: 22). It addresses emotion, reason, and heart, and, therefore, the common people and experts at the same time.

It has been shown that the language of the Qur'an exhibits some striking instances of balance, with some word pairs showing exactly equal numbers of occurrences. For example, we have antonyms as follows:

Word	Antonym	No. of occurrences of each
al-ḫarr ('heat')	*al-bard* ('cool')	4
al-ḫāya ('life')	*al-mawt* ('death')	145
al-kufr ('disbelief')	*al-īmān* ('belief')	17
kufr ('disbelief')	*īmān* ('belief')	8
al-nafʿ ('advantage')	*al-fasād* ('drought')	50
al-rahba ('fear')	*al-raghba* ('courage')	8
al-ṣāliḥāt ('good actions')	*al-sayyi'āt* ('evil actions')	167
al-ṣayf ('summer')	*al-shitā'* ('winter')	1
al-ṭuma'nīna ('quiet')	*al-ḍayq* ('anxiety')	13

We also have synonyms:

Word	Synonym	No. of occurrences of each
al-'aql ('reason')	*al-nūr* ('enlightenment')	49
al-ḍālūn ('those who go astray')	*al-mawt* ('death')	17
al-ḫarth ('tilling of ground')	*al-zirā'a* ('agriculture')	14
al-jahr ('publicity')	*al-'alāniyya* ('publicity')	16
al-qur'ān (the Qur'an)	*al-waḥy* ('revelation') and *al-islām* (Islam)	70
al-'ujb ('pride')	*al-ghurūr* ('impostor')	27

We also have pairs denoting antecedent and consequence:

Antecedence	Consequence	No. of occurrences of each
al-bukhl ('avarice')	*al-ḫasra* ('regret')	12
al-fākhisha ('shameless')	*al-ghadab* ('anger')	26
al-infāq (giving alms)	*al-riḍā* ('devoutness')	73
al-kāfirūn ('unbelievers')	*al-nār* ('hellfire')	154
al-zakā ('purity')	*al-baraka* ('blessing')	32

The Qur'an does not conform to standard notions of poetry, either, as it has its own rhyme schemes. Chapter 49, for example, uses different rhymes, as verses 1, 3, and 5 end in 'm' (*mīm*), whereas verses 2, 4, and 6 end in 'n' (*nūn*). However, verse 7 ends in n instead of m, whereas verse 8 concludes with m instead of n. Then it changes its pattern yet again, as verses 9, 10, and 11 end in n. This absence of a coherent scheme is characteristic of most of the verses that follow in this part of the chapter. The Qur'an even introduced something that puzzled even Muhammad's contemporaries, for some of its chapters begin with isolated letters. Thus, chapters 38 and 50 begin with one single letter – Ṣ (Ṣād) and Q (Qāf), respectively – whereas chapters 20 and 36 are referred to by their opening letters – Ṭ-H (Ṭā'-Hā') and Y-S (Yā'-Sīn), respectively. Chapter 68 opens with the letter N, but it is usually called The Pen instead of N. Thirteen chapters of the Qur'an begin with the same two letters, i.e., letters Ḥ-M (Ḥā'-Mīm) – chapters 40, 41, 42, 43, 44, 45, and 46 – whereas chapters 20, 36, and 27 start with Ṭ-H (Ṭā'-Hā'), Y-S (Yā'-Sīn), and Ṭ-S (Ṭā'-Sīn), respectively. Chapters 10, 11, 12, 14, and 16 of the Qur'an start with the letters A-L-R (Alīf-Lām-Rā'); Chapters 2, 3, 29, 30, 31, and 32 with the letters A-L-M (Alīf-Lām-Mīm); and Chapters 26 and 28 with the letters Ṭ-S-M (Ṭā'-Sīn-Mīm). Chapter 7 begins with the four letters A-L-M-Ṣ (Alīf-Lām-Mīm-Ṣād). Finally, chapter 19 (Maryam) starts with the five letters K-H-Y-'A-Ṣ (Kāf-Hā'-Ya'-'Ayn-Ṣād). All chapters that bear names of prophets open with letters, except for chapter 47 (Muhammad). Likewise, every single chapter of the Qur'an should begin with a reading of the *basmalla* (In the name of God, the Most Merciful, the Most Beneficent), but it is prohibited to recite it at the start of the chapter 9 (Repentance).

Instead of being restricted to specific literary rules, the Qur'an introduced different literary styles. It, for example, uses short but comprehensive sentences like the verse 2: 179 "wa fi-l-qiṣāṣ ḥāya" (there is life in *qiṣaṣ* – a sentence to a killer) to satisfy the most

eloquent thinkers, who insist that the best sentence is the shortest but most comprehensive. This style, called *ījāz qisār* (making less words but more meanings), is the best kind of *ījāz*, for to express the same meaning otherwise would require more words, such as "if a murderer is murdered, the punishment will prevent others from killing." This process will result in people's lives being saved. However, the Qur'an's eloquence, for Ibn Hazm in support of al-Nazzam, was not a miracle. He even dismissed such a notion as an act of disbelief because it contradicts the Qur'an 4: 150–151. These verses require absolute belief in the entire Qur'an, so that the belief in certain verses as evidence of the Qur'an's divine eloquence amounts to disbelief of the same in other verses. In this way, Ibn Hazm tried to transpose the Qur'an's language from an Arab mindset to an Islamic one.

Sarfa, after all, had its roots in the Mu'tazilite concept of the createdness of the Qur'an, a theory that Caliph al-Ma'mun used to unify his divided empire. Both al-Amin and al-Ma'mun were sons of Caliph Harun al-Rashid, but by different mothers: Al-Amin by an Arab mother, and al-Ma'mun by a Persian one. The elder al-Amin ruled the Abbasid Empire on the death of their father in 809, whereas al-Ma'mun became governor of the eastern provinces of the Empire. Al-Amin's Arab advisers encouraged him to eliminate his half-brother, resulting in a civil war (809–813) that al-Amin lost. One of al-Ma'mun's policies as a newly installed Caliph was to impose his unifying ideology of mihna (inquisition): every official of the Abbasid Empire had to declare his acceptance of the createdness of the Qur'an. Because the Qur'an is created, the new ruler might not need the Arab ulama to interpret it because it is a 'secular' book, while attracting the support of non-Arab segments of his subjects. Theologically, he implied that the Qur'an was parallel to Jesus: both were created. Under the leadership of Ahmad ibn Hanbal (the founder of Hanbalism), however, al-Amin's supporters condemned al-Ma'mun's theory as unbelief. In its place, they proposed Ibn Hanbal's concept of the eternity of the Qur'an. The createdness of the Qur'an lasted until the Caliph al-Mutawakkil (r. 847–861) replaced it with Ibn Hanbal's theory. This 'orthodox' ideology was called Sunnism in contrast to Mu'tazilism.

In 1774 Ibn 'Abd al-Wahhab revived Hanbalism under the pretext to call for a return to the Qur'an and Hadith. By contrast, Ahmad Khan started his Neo-Mu'tazilism – known as Islamic modernism – in India right after the 1857 abortive Mutiny. Unlike Ibn 'Abd al-Wahhab, Khan believed that Gabriel was not an ambassador who brought the messages of God to Muhammad. Khan also rejected Shah Wali Allah's theory of 'speech of God,' i.e., that Muhammad received the ideas from God and reformulated them in his own words, as God, for Khan, poured both the contents and words of the Qur'an to Muhammad's heart. In his 'the Prophet's mind,' Fazlur Rahman believes that Muhammad received only ideas from God and reformulated them in his own terms, whereas Hassan Hanafi differentiates between theory of prophecy and hermeneutics. The former deals with the vertical communication between God and Muhammad: Gabriel dictated the words of God to him who in turn dictated them to the inscribers of revelation immediately at the time of their utterance so that they have been preserved in writing until today. This constitutes the verbatim language and ideas of the Qur'an, since Muhammad was a passive transmitter. However, hermeneutics deals with the verbatim revelation horizontally, as it interprets the Qur'an after its transmission and recording. Interpreters, including Muhammad, are active. The occasions of revelation, however, indicated the human need for solutions to contemporary problems, to which the Qur'an responded. Therefore, the occasions of revelation are 'secular,' as they represented the priority of human thought over revelation.

R

(R) as a Variable

J M Scobbie, Queen Margaret University College, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

All sounds are variable, but some are more variable than others. Does **hyper**-variation mean a greater disposition for sociolinguistically relevant conditioning, or, alternatively, a tendency for relatively greater noisiness in the distribution of unconditioned variants? Whatever the case, there should clearly be a special interest in the sociolinguistic systemization of those sounds that are so unusually prone to variation that it is difficult to capture them within a simple articulatory and acoustic definition. Such is the case with the sociolinguistic variable (R).

About three-quarters of languages have at least one /r/ phoneme (Maddieson, 1984), but since the class of rhotic sounds is widely acknowledged to be very varied, the definition of /r/ must be flexible, and the definition of 'rhoticity' is rather heterogeneous and perhaps even somewhat arbitrary (Ladefoged and Maddieson, 1995). The fundamental problem arises from the tension between a simple phonological claim that "language L has a phoneme /r/," the fact that /r/ tends to be an isolated phoneme rather than a member of a larger natural class, and the astonishingly nondeterministic correspondence between an /r/ and the crosslinguistic range of possible phonetic exponents involved. Moreover, some of the phonetic sounds concerned (e.g., velar fricatives) behave systematically as nonrhotics in other languages. Indeed, pedagogic texts often rely on such correspondences to teach pronunciation (e.g., the sound of French /r/ is like the sound at the end of the Scottish pronunciation of 'loch'). The use of the wrong /r/ sound can create the impression of a very strong foreign accent for those learning standard varieties, but tolerance in the face of idiosyncratic variation and/or the acquisition and use of sociolinguistically conditioned variation seems to be the norm among native speakers.

Although variability is even more characteristic of vowels, vowels occur as members of a larger system and can freely, in time, change phonological identity as they change phonetic quality from one location to another. However, the single label /r/ is used for a much wider and emptier phonetic space. We can thus understand John Walker's rather pejorative-sounding opinion from 1791 that in English /r/ is "the most imperfect of all the consonants" (Harris, 1994: 230).

Nevertheless, there are some grounds to identify rhotics as a natural class. First, a number of phonetic sounds can be and have been classed as **exclusively** rhotic, especially (nonlabial) trills and retroflex approximants. Second, diachronic change can be seen to affect the phonetic characteristics of rhotics without leading to their loss as a contrastive element, giving rise to wide crosslinguistic variation in the form of the same rhotic in related languages. In Western Europe, for example, cognate words can employ alveolar or uvular trills, as well as labials, dentals, alveolars, velars, uvulars and labiodentals (fricatives and approximants), and even vowels. These various forms (apart from the last: cf. Barry, 1995) are usually regarded as the result of phonetically superficial and not phonologically meaningful changes. Third, structurally conditioned allophony and variability of the /r/ within a single language reinforce the correspondence of heterogeneous phonetic variants to the same phoneme. Analogous to the diachronic situation, the phonological system of a single language can lead us to postulate a single phoneme /r/ (superficially being voiced or voiceless, fricative, tap, or approximant). Fourth, sociolinguistic conditioning of variation in a rhotic is common within a language. Fifth, developmental data often show a range of exponents of /r/ from infancy into adulthood.

It is important to understand the descriptive phonetic nature of rhotic variation, though we need not worry here about the deeper question of why such an apparently disparate set of sounds is related (see Ladefoged and Maddieson, 1995; Barry, 1997). Without some phonetic preliminaries, it is hard to appreciate an understanding of sociolinguistic conditioning of (R) in any particular situation, and, moreover, it is hard to see the extent to which any findings may transfer from that situation to another with the

'same' variable (R): such a comparison may make very little sense. The next section, therefore, is a review of the wide range of phonetic variation of rhotics. It should be clear that /r/, because it is prone to vary in many and subtle ways, should both be an opportunity and a challenge to variationists. Then the ground will be clear to move on to more concrete detail of sociolinguistic variable (R), mainly in the context of British English.

What Can Be an /r/?

In general, the label /r/ seems to be applied to oral lingual sonorant consonants unless they are specifically palatal, lateral, or labial. It is hard to avoid the feeling that /r/ is therefore something of an 'elsewhere' category. If it were not for the fact, mentioned above, that it is often possible to provide phonological, sociolinguistic, diachronic, or acquisitional justification for the establishment of the category, it would be tempting to acknowledge '/r/' to be a rather meaningless label. For phonological theories favoring underspecification and featural analysis, the problem is to choose an appropriate abstract feature for /r/, derive common and uncommon aspects of its phonological behavior from this abstract specification, and then explain why the phonetic realization of this abstract /r/ is both systematic and arbitrary. For theories positing highly detailed mental representations, the problem is to explain how an abstract category /r/ is formed from articulatory and acoustically diverse input.

From the point of view of discussing the phenomenon of rhoticity, however, '/r/' or '(R)' are labels as good as anything else, so long as we recognize the descriptive and theoretical limitations arising from the use of this convenient international phonetic alphabet or orthographic symbol.

In looking for a more realistic description of rhotic sounds, we should refer first to Lindau's influential acoustic crosslinguistic study of rhoticity (Lindau, 1985) and to the excellent Ladefoged and Maddieson (1995: Chapter 7). Lindau's starting points were, on the one hand, the heterogeneity in the phonetic characteristics of /r/ crosslinguistically and its allophonic heterogeneity, and on the other, the phonological homogeneity of the distribution of /r/ and of the effects of /r/ on neighboring segments, especially vowels.

In looking at about a dozen phonetic types of /r/ from multiple speakers of four Indo-European languages and in a more varied range of seven West African languages, Lindau demonstrated some of the similarities and differences that can be found for some common rhotic sounds. The phonetic details are relevant to an understanding of rhoticity in itself, and as a pointer to the type of fine differences that can be learned and therefore function sociolinguistically. For example, the ways in which uvular and apical trills are distinguishable acoustically do not seem much clearer than the ways in which apical trills can differ. With respect to the spectral patterns of the trills, the third spectral peak is quite low in Chicano Spanish, but "other forms of Spanish from Argentina, Colombia, and Mexico display a much higher third spectral peak than the Chicano Spanish, indicating a more dental place of articulation. The low third spectral peak in Chicano Spanish may be due to influence from English" (Lindau, 1985: 161). Thus, it is clear how the broadest detail for an /r/ may be adequate for phonological researcher, but even a relatively careful '[r]' or '[ɹ]' may be too coarse to indicate the existence of variation within a dialect or community: "even in languages where a possible realization is a trill, not all speakers use a trill, and the speakers that do, have tap and approximant allophones as well as the trill" (Lindau, 1985: 161). In her sample of trilling languages, about half the speakers produced trills. Spanish, with a tap-trill contrast, had a high proportion of phonetic trills, whereas only three of 10 Swedish speakers produced trills. This could have a phonological cause – namely that Swedish has only one rhotic phoneme – or a phonetic one, such as uvular trills being less easy than alveolar ones to produce consistently. Similarly, "taps are not produced in the same way in different languages, nor are they always produced in the same way by different speakers of the same language" (Lindau, 1985: 161). Ladefoged and Maddieson (1995) presented numerous further examples from a wide range of languages.

Lavoie (2001), in a highly detailed study of Mexican Spanish (and American English), also found some speaker variation, particularly in how weakened the trill was in a weak (nonprestress) position, but also a great deal of positional and random variation. She calculated variation in the trill and tap phonemes with respect to their manner of articulation. The Spanish tap phoneme was very variable in manner, while the trill was more consistent.

Further subtle variations are possible and can be observed. For example, in many languages, prepausal trills may be more or less devoiced. Greater or lesser amounts of epenthesis can occur between consonants and a following tap or trill, leading even to changes in the syllable count. And, of course, they may be in a rich variety of positional variation with nontrills.

Approximant /r/ is, of course, even more open to variation. It may be smooth, vocoid, and friction-free, indicating a constriction no tighter than that found in vowels and glides, and therefore characterized by

formant transitions of rapidly changing or fairly static character, largely depending on the vowel context and syllable position of the /r/. A retracted or retroflex approximant will have long transitions flanking it, particularly between it and a preceding high or front vowel, and these transitions can become like a diphthongization of the preceding vowel and help cue the presence of /r/ as much as reaching the target does. Thus a retroflex target can be replaced by a centering diphthong, and a correspondence between /r/ and schwa is established. Nonhigh vowels may, on the other hand, coalesce with /r/ and can result in a rhoticized vowel.

For approximant /r/, typically the third formant is lowered, compatible with pharyngeal and/or postalveolar constrictions (Stevens, 1998). Indeed, these two constrictions have been observed in many articulatory studies, often together with lip rounding, which serves to lower both the second and third formants. Thus, we begin to see that approximant /r/ may be produced with multiple constrictions, or that alternative constrictions can be used, giving rise to broadly similar acoustic output. Articulatory complexity and flexibility are therefore characteristic of /r/ and perhaps are among the sources of its tendency toward variation and change.

While anterior approximant /r/ can also be rather fricated, frication is a more typical characteristic of non-trilled uvular and velar /r/. They range widely in the degree of noise and devoicing. Finally, the anterior lingual configuration of a postalveolar approximant /r/ can vary between basically retroflex or bunched configurations.

In sum, there is no natural articulatory or acoustic class that is easy to define; nor is there a set of sounds (however constituted) that can be said to be exclusively rhotic. Taps and flaps can also be variants of stops, laterals, or nasals. A fricative may be the phonetic realization of a phonological rhotic but may also be, of course, a fricative. And while pharyngeal or labial /r/s seem to exist, more often than not, approximants in those regions are not classed as rhotics without further systematic reasons to do so. Lindau's conclusion that rhotics exhibit a Wittgensteinian familial resemblance remains the key insight to take into any sociolinguistic study of (R).

Sample Studies of (R)

English is not unusual in having an /r/, in having only one rhotic phoneme, or in having stronger and weaker variants of it in relatively predictable phonological contexts. Indeed, in the Germanic context it is one of a number of languages (German, Dutch, Danish, Swedish) with both rhotic and nonrhotic dialects. The so-called r-less or nonrhotic dialects do not lack an /r/ altogether. Rather, /r/ is, in broad terms, missing from syllable codas in nonrhotic dialects. Like vowel variation, (R) in the English-speaking world can therefore a useful variable for the sociolinguist and indeed has appeared in a number of studies, including foundational work in the field (Labov, 1966; Labov, 2001). Although the focus here is on accessible reports of English variation, we should note that there are a few very large-scale studies in other languages that specifically address (R). A fair bit of work has been done on Dutch, most notably the ongoing 'Hema' project under the direction of van Hout, Van de Velde and Zonneveld (cf. Sebregts *et al.*, 2003). (See also the attached multimedia materials collected in collaboration with Sebregts.) For French, there is a major project 'La phonologie du français contemporain: usages, variétés et structure' under the direction of Durand, Laks and Lyche (cf. Delais-Roussarie and Durand, 2003). (See also Chevrot *et al.*, 2000; the hard-to-obtain Van de Velde and van Hout, 2001; and a successor volume in preparation; Gordon, Campbell, Hay, Maclagan, Sudbury and Trudgill, 2004; Hay and Jannedy, forthcoming, with more on (R) in New Zealand.)

The situations in North America, Scotland, and Ireland are rather different from the situations in other English-speaking regions. They are predominantly rhotic systems in which rhoticity is associated with prestige or standard speech. Elsewhere, however, nonrhotic speech tends to be the standard. It is useful, therefore, to examine the systems found for (R) in the British Isles, for example, since it is not only representative of both directions of variation, but the locations are also close enough that there is likely to be some tension and mutual influence. Variation in the United Kingdom is long-standing, as is evident in, for example, the *Survey of English dialects* and sources therein (Orton and Dieth, 1962a, 1962b; Upton and Widdowson, 2004). Walker (1791) noted alveolar and uvular trills and even nonrhoticity in London, where the /r/ was "sometimes entirely sunk" (Harris, 1994: 231).

Sociolinguistic studies of /r/ are concerned with phonetic variation in /r/, variation in the phonotactic distribution of /r/ (and other segments conditioned by /r/), and, crucially, the interaction between the two. Loss of coda /r/ ultimately means vocalization and leads to an expanded vowel system and/or mergers. The loss of coda /r/ results diachronically from progressive phonetic weakening of more consonantal productions until the productions are at first similar to vowels, then merged with them. Exactly how the reduction in the phonetic rhoticity of /r/ interacts with

an increasingly merged set of vowels before /r/ is still unclear, but it is likely that breaking, in which the vocalic transitions into /r/ gain in salience, is often involved (Wells, 1982; Barry, 1995).

Yet different rhotic accents of English can have larger or smaller vowel inventories before /r/, making /r/ responsible indirectly for yet more variation. For example, while some rhotic American accents merge 'Mary,' 'merry,' and 'marry,' rhotic Scottish accents tend to preserve these distinctions, as well as keeping 'horse' and 'hoarse' distinct. Scottish English has perhaps the fewest number of vowel mergers before a phonetically consonantal /r/; this makes it a particularly interesting accent for internal reasons, as well as on account of its social and geographic proximity to nonrhotic Standard Southern British English. In Scotland, many speakers of Standard English have a basic 12-vowel system and merge only /ɪ/ and /ʌ/ before /r/ ('fir' and 'fur').

Even in rhotic accents, weak syllables are apt to lose /r/, especially before a consonant word internally ('surprise,' 'forget') or in frequently used word-final sequences ('other than'). In Scotland, the general phonotactic profligacy of coda /r/ attests to the survival of a more strongly consonantal coda /r/ than many other British varieties, but one that is, nevertheless, beginning to weaken from the coda into the nucleus structurally, as it has weakened phonetically in previous generations. The (contextually devoiced) trill or tap so consciously caricatured by Scots themselves as well as by outside observers seems largely gone, having being replaced by an approximant among younger and less vernacular speakers. Variation as a result of structural factors is common too. A speaker may have a lingual approximant /r/ (retroflex or alveolar) generally in onsets, but affricates in /tr/ and /dr/ clusters, and a tap in labial clusters such as /br/. Emphatic stress can result in a higher frequency of occurrence of taps and trills.

Recent sociolinguistic research in Scotland has shown how /r/ varies, and by implication how it is changing phonetically and socially. It may be, indeed, that such work reveals the early stages of the change toward phonological nonrhoticity. It is far from obvious that this is a simple change from above under the influence of Standard Southern British English. Such a change has been predicted among professionals and laypeople alike, given the high degree of nonrhoticity among children of English incomers, who tend to be middle class, causing loss of /r/ through contact. Such direct influence has been particularly obvious to many informal observers of middle-class speech in Edinburgh, in which Scottish Standard English shades off into clearly English-influenced accents (see Romaine, 1978).

It is therefore most important that a quite different and surprising behavior was confirmed by Jane Stuart-Smith's variationist examination of the English of Glasgow, the largest city in Scotland. Glasgow accents are stigmatized by Scots and non-Scots alike due to its strong Scots vernacular character, and Glaswegians display a great range of variation as a consequence. In Stuart-Smith's fieldwork (undertaken in 1997), 32 speakers were studied, bisected into groups of male and female, younger (13 or 14 years) and older (40 to 60 years), and working and middle class. Both spontaneous and word list speech was collected. In Stuart-Smith (2003) the results were compared to two previous important datasets collected by Macaulay (in 1973) and Macafee (in 1984–1985), which provide real-time support for Stuart-Smith's apparent time study, and to previous variationist work with more of a focus in Edinburgh by Romaine in the 1970s and by Speitel and Johnston in the 1980s, both of whom provided some earlier indication of variation in (R), including vocalization in working-class speakers (e.g., Romaine, 1978; Johnston, 1997).

The important point about this work is that the situation is far more complex than might be expected. While nonrhoticity has been spreading slowly across the United Kingdom for centuries, although perhaps more slowly than generally thought (Gordon *et al.*, 2004), rhoticity has seemed relatively secure and prestigious in Scotland. On the other hand, phonetic weakening of /r/ to an approximant in Scottish Standard English is extremely widespread. Indeed, although it is typical of a phonological or phonetic variable like (R) to be gradient, the behavior here is approaching categoricalness.

The 1997 Glasgow study made it clear that there has been both a loss of postvocalic phonetic rhoticity and phonetic variation in the realization of /r/. While nonrhotic patterns are **not** particularly evident in middle-class speech, the same cannot be said for working-class speech. Unsurprisingly, the range of variants transcribed is large. Common variants include central approximants, retroflex approximants, alveolar taps, retroflex taps, and vowels. Less common variants include alveolar trills and uvular fricatives.

First, Stuart-Smith reported an analysis of /r/ in all positions in the word list data, plus a 10% sample of the spontaneous speech. In the read speech, working-class girls formed a group on their own that was statistically distinct from all middle-class groups. Their main characteristic was a complete avoidance of retroflex approximants and heavy use of vocalization for coda /r/. Additionally, tendencies were noted across read and spontaneous speech. Younger and older working-class women seemed to differ,

while young working-class women resembled young working-class men. They both vocalized a great deal and avoided retroflex approximants. For all speakers, alveolar taps were well-represented, but trills and retroflex taps are almost absent.

Second, Stuart-Smith presented a more detailed study (all spontaneous data for all subjects in addition to the word list data) of coda /r/ and its vocalization. It was examined with respect to various phonological subenvironments. Preconsonantal and word-final /r/ were examined separately, and the latter was subdivided into two independent groups, namely stress (/r/ in a lexically stressed versus unstressed syllable) and structure (prepausal, preconsonantal, and prevocalic).

The extensive number of phonetic variants were allocated into what I will call rhotic, vocalic, intermediate, modified vocalic, and rhoticized vowel categories. In general, middle-class speakers used a rhotic consonant, while working-class speakers used a far wider range of variants. The working-class teenagers, particularly the girls, favored vocalization. The polarization of the young working class and the other groups was most evident in the stressed prepausal position, for here vocalization was found at high levels for boys and girls alike. However, preconsonantally (e.g., 'card'), the working-class girls favored a plain vowel, but the working-class boys favored a modified (velarized) vowel. In unstressed prepausal syllables, the use of plain nonrhoticized vowels by the girls was almost categorical. This suggests the girls may have been closer to the merger of r-ful and r-less words and to phonological nonrhoticity, and were furthest from the rather homogeneously rhotic middle-class speakers. The use of modified vowels by the boys may have been the result of the preservation of velar, pharyngeal, or other dorsal secondary articulations, due ultimately to the gesturally complex nature of some speakers' approximant /r/. But since those who vocalized most tended to use plain vowels, those reflexes of /r/ may well have been evidence of a stage in the weakening of /r/, in which speakers' outputs contained a gesturally reduced but still identifiable /r/.

Future research will hopefully reveal the extent to which (R) is like other variables, both consonantal and vocalic, in Glasgow, as well as how the changes in /r/ have arisen and been transmitted.

A further issue brings us back to the problem of the phonetic variability of rhotics in the first place: the nature of the hard-to-discern articulatory underpinning of /r/. Instrumental acoustic analysis can help to uncover subtle sociolinguistic patterning, but in the case of (R), another technique may be able to shed more light on such questions – namely, articulatory ultrasound. The technique is noninvasive and offers great opportunities for use in the analysis of spontaneous speech and in large-sample studies. See the associated multimedia files for examples of Dutch and Scottish speakers.

Ultrasound can provide tongue-surface movies of the midsagittal section of the tongue and can clearly reveal different articulatory strategies for anterior approximant /r/, even without detailed analysis. The multimedia files provide examples of two young adult middle-class speakers from the Edinburgh area with acoustically similar formant structure for /r/, and impressionistically similar /r/, have different underlying articulations. One has a retroflex or alveolar approximant with a tip-up articulation and, it seems, with no accompanying pharyngeal gesture. The other has a bunched or tip-down production with a clear postalveolar constriction and a pharyngeal constriction. It may be that the use of modified-vocalic productions of /r/ in the 1997 Glasgow data indicate a posterior constriction, too. A stratified multisubject study with acoustic and ultrasound analysis is certainly feasible, whereas other articulatory techniques would be far more invasive and probably incompatible with unmonitored spontaneous speech.

In nonrhotic areas of the United Kingdom, one of the major phonological phenomena in English can be observed, namely 'r-sandhi' ('linking-r' or 'intrusive-r'). Despite its high frequency of use, the nonetymological aspects of intrusive-r are perhaps responsible for a certain amount of conscious awareness of the phenomenon and resultant social and stylistic variation. Foulkes (1997) conducted the first large sociolinguistic study of the phenomenon (in Newcastle-upon-Tyne and Derby), although other research has examined the phenomenon in prestige and broadcast English. In Newcastle, linking-r and intrusive-r were less common than in more southerly accents and were associated with middle-class speakers. The frequency of linking-r use among young working-class speakers was only approximately 40 percent, compared to about 80 percent of older middle-class speakers. The rate of intrusive /r/ use in working-class speech was only about 20%. Interestingly, style did not behave in this study in the way that it is normally assumed to work: middle-class speakers used **more** intrusive-r in word list reading than in spontaneous speech.

Another topic of much interest, especially in nonrhotic Britain, is the recent increase of strongly labiodental productions of /r/ (Foulkes and Docherty, 2000). A few decades ago, an adolescent or adult with such a variant would be seen as having an idiosyncratic or even pathologically delayed production (with some very specific sociolinguistic exceptions), whereas recent research revealed that, increasingly, a significant minority of young adults can be found

with labiodentals. Indeed, it is by no means an infrequent characteristic of younger professional broadcasters in the United Kingdom. Recent informal observation of nonbroadcasters interviewed on United Kingdom radio and television suggested that between 25 and 50 percent of speakers used a labialized /r/ at least some of the time, at least as judged by this retroflexed, rhotic, and Scottish listener. This impression echoes Peter Trudgill's 1983 Norwich data (Trudgill, 1988), where few subjects with clear labiodentalization could be said to use it ubiquitously or consistently strongly.

Intervocalic /r/ behaves rather differently from prepausal or preconsonantal /r/. Intervocalic position is a rhotic position, but may be prosodically weak, particularly if it follows a stressed syllable and precedes an unstressed syllable. So loss of intervocalic /r/ sometimes occurs (and see also loss of prevocalic /r/ in weak syllables, e.g., 'pretend'), but it is likely to be differently distributed than plain nonrhoticity. In England and the United States, high-frequency forms like 'very' can be found with an almost monosyllabic pronunciation, and in more formal lexis, such as 'heroin,' the /r/ may be merely a hiatus between the vowels with no percept at all of a consonant. In England, this type of production seems particularly common among users of labial /r/. It marks the phonetic low-point of rhoticity, in which /r/ can appear as even less than a schwa or vowel offglide, namely as a hiatus between syllables. Since nonrhotic English did not previously permit sequences of nonhigh vowel plus vowel (this being the trigger for r-sandhi), such ultimate weakening of /r/ to hiatus does not (yet) cause any mergers in those accents.

Labiodental /r/ provides yet more evidence of how phonetically heterogeneous the class of rhotics can be. With heavily labialized /r/, bilabial trills corresponding to the clusters /br/ and /pr/ can even be found.

Acoustic analysis by Mark Jones (personal communication) and my own ultrasound analysis show that 'labiodental' /r/ is at an end of a phonetic gradient that even in its most extremely labialized forms is quite distinct from /w/, that it is favored in labial contexts, and that it may be a result of the boosting and early onset of the labial gesture that is already present in approximant lingual /r/ in the United Kingdom. In other words, postalveolar and pharyngeal lingual gestures may still be present in a 'labiodental' /r/, functioning to distinguish /r/ from labial-velar /w/.

As an aside, in the 1997 Glasgow study (Stuart-Smith, 2003) no labialized /r/s were found outside labial contexts, and informal observation suggests that these variants appear only sporadically in rhotic and nonrhotic Scottish adults. Labialized /r/ and nonrhoticity are, however, somewhat in evidence in child development in Scotland, as they are in the United States. However, such productions are not common, or at least were not so in the late 1960s, as evidenced by a large (510 subjects) standardized study (Anthony *et al.*, 1971) of children aged 3.0 to 5.6. Out of 510 productions, labialized /r/ was more common in /br/ (32 tokens in 'bridge,' 26 in 'toothbrush') than /str/ (22), /kr/ (18), or /tr/ (16). However, in /θr/, nonlabialised /r/ was very common, even after [f] (225 tokens). Only 15 tokens were [fw], and another nine were labial. Initial /r/ ('red') was only 86% 'correct' (i.e., trill, tap, or lingual approximant) by 5;6. Overall, 25 productions were [w], 12 were [vɹ], six were [ɥ], three were [ʋ], and three were [βɹ]. Medial /r/ ('garage') was labialized in 38 tokens. Finally, nonrhoticity in a weak syllable ('soldier' and 'birthday') was so common that absence of /r/ was not even counted as an error.

Foulkes and Docherty (1999) collected reports from a number of sociolinguistic studies on urban varieties throughout the United Kingdom and discussed the various phenomena affecting /r/ with reference to in a number of cities. Focusing mainly on nonrhotic varieties, the following were observed. Labial forms of /r/ were found in London (where they are a long-time variant), Norwich, Milton Keynes, Reading, Hull, Newcastle, and Derby. In nonrhotic Newcastle, the standard approximant /r/ was supplemented by taps in intervocalic position, and the local Northumbrian 'burr' ([ʁ]) was rare and found only in rural areas. Generally, nonrhoticity and intrusive-r were the norm for accents with labialized /r/, especially among the young. In nonrhotic Derby (see also Foulkes, 1997), linking-r was categorical and intrusive-r present in about 55% of possible contexts, with no sociolinguistic patterning. In Sheffield, Cardiff, and Sandwell, the norms were non-rhoticity, a lingual approximant /r/ realization, and intrusive-r. Finally, it was noted that other phonological changes could increase the number of environments in which intrusive-r can operate. As well as after vocalized /l/ or before dropped /h/, reductions of full vowels to schwa resulted in intrusive-r, so words like 'window' varied, depending on whether a reanalysis of the final vowel as /ə/ had occurred, and the infinitive 'to' was also rather variable in its conditioning of an intrusive-r. Sandhi was particularly common in combined forms like 'gonna' and 'wanna.' Finally, in London, monophthongization of vowels in the MOUTH and GOAT classes may also have fed intrusive-r.

In North America, a primarily rhotic continent, a number of foundational and influential sociolinguistic studies have addressed (R) (see Wolfram and Schilling-Estes, 1998). It should first be noted that

taps and trills are uncommon in North America, presumably because an alveolar tap or flap is used for /t/ and /d/ in just those environments in which tapped /r/ is likely in British English, and although the mechanisms are not identical, if a tap were used in 'berry,' it might merge with 'Betty.' Tapping of /t/ and /d/ is not normally regarded as a rhoticization in the United States, and there appear to be no grounds, at present, for viewing it as such.
